

Chapter 0

Introduction

1. We are trying to understand Mizar. So I am transcribing the source code into a literate program, following the order of compilation. Perhaps this “goes against the spirit” of literate programming, but it makes the most sense to understand what is going on for programmers.

We will begin with the “Parser module” (`base/parser.pas`), and all the dependencies needed to compile it. For clarity (or at least ease of reference) each “chapter” appearing in the table of contents corresponds to a different file.

We are studying Mizar’s source code as of Git commit `9e814a9568cfb44253d677e5209c360390fe6437` (dated 2023 October 11).

2. Files are chapters. We will organize the text by compiler dependencies. It makes sense to treat each file as a separate “chapter”. With the exception of this introductory chapter (“chapter 0”), all future chapters are called “File n ”.

Just as Knuth’s *T_EX: The Program* (Addison–Wesley, 1986) was organized into modules which are presented “bottom-up”, each module is discussed and programmed “top-down”, we shall try to do likewise. File $n + 1$ can only depend on code appearing in Files 1 through File n .

There are natural ways to “cluster” the discussion in each File, which motivates the “section” and “subsections”. Each section (*but not subsections!*) starts on a new page, written in sans serif bold prefixed with explicit an “Section”. Subsections are written in sans serif bold prefixed with an explicit “Subsection”, with vertical whitespace separating it. This chapter has two sections (one discussing the flow of Mizar, and the other enumerating observations and “to do” items).

3. Each chapter is written using numbered paragraphs, since we are using Donald Knuth’s **WEB** to write a literate program. References will be made to the paragraphs. Index entries give the paragraph numbers associated with each entry. And even though I just used the term “paragraph number”, they really group several paragraphs into a unit of writing.

Paragraphs are numbered *independently* of chapter, section, subsection. This is a quirk of **WEB**. This was how Mathematicians wrote texts back in Euler’s day. We will refer to a paragraph by writing (§ n) to refer to paragraph n . Again, this was the conventions used by Euler.

Each paragraph consists of three parts: the “text part” (informal prose written in English), the “macros part” (which introduces macros written in the **WEB** language), and the “code part” (which contains a pretty-printed snippet of PASCAL code). A paragraph may omit any of these parts but has at least one of them. Thus far, all our numbered paragraphs have consisted of “text parts” only. The “code part” can optionally have a name in angled brackets. If the name is missing, then it continues the previous chunk of code from the previous numbered paragraph.

4. The Mizar program is released under the GNU license. So let us place this license in one place early on. (This is an example of a numbered paragraph with a “named code part”.)

⟨GNU License 4⟩ ≡

{ This file is part of the Mizar system. Copyright (c) Association of Mizar Users. License terms: GNU General Public License Version 3 or any later version. }

This code is used in sections [35](#), [80](#), [89](#), [127](#), [151](#), [153](#), [167](#), [185](#), [198](#), [307](#), [612](#), [617](#), [646](#), [674](#), [714](#), [748](#), [807](#), [841](#), [879](#), [895](#), [1030](#), [1373](#), [1379](#), and [1672](#).

5. System dependent assumptions. We will note system dependent code when appropriate, but implicitly we will assume we are working with users on a UNIX-like operating system. Hardware should not matter (barring antiques from the 1960s or earlier). We will cite the POSIX standard when appropriate, but only for the sake of discussion of things like “How long can we expect a filename to be?” (POSIX says the maximum length of a filename is Operating System dependent, but must be at least 14 bytes long.)

6. Asides and opinions. Some paragraphs will be labeled as “asides” which are tangential remarks not directly relevant to understanding the code, but will enrich the reader’s life. [[The author will offer opinions about the design and implementation of Mizar in parenthetical sentences like this one, surrounded by double brackets.]] If the reader is unsatisfied by the arbitrary opinions of a random programmer, then they can disable the asides by redefining the `\Ithink` macro to have an empty body.

7. Aside: Typography of “Modern” PASCAL. We will be following the typographical style as found in Niklaus Wirth’s *Algorithms + Data Structures = Programs* (Prentice–Hall, 1975) and Donald Knuth’s *T_EX: The Program* (Addison–Wesley, 1986). But there are a few typographical situations which requires thinking hard about, since “classical” PASCAL does not have *object* or inheritance (or *unit* modules).

First, we need to know that “modern PASCAL” differs from the PASCAL Knuth worked with, in several ways. Mizar uses “units” which are a module system introduced by UCSD PASCAL (*c.* 1977). We will need to format them for `WEAVE`.

Documentation and tutorials frequently compare **unit** to **program**, so we should probably typeset it as such. The big question is whether the **interface**, **implementation**, and **uses** keywords are **var**-like or **const**-like. I ultimately decided for the latter (since **var**-like typography would have them appear in the index underlined).

We will treat **implementation** typographically *as if* it were a **const** because the **end** will not be indented properly otherwise.

```
format unit ≡ program
format interface ≡ const
format implementation ≡ const
format uses ≡ const
```

8. Objects appear in Free PASCAL, and they behave like records. There are also **constructor** and **destructor** functions.

```
format object ≡ record
format constructor ≡ function
format destructor ≡ function
```

9. Primitive functions. We have several primitive functions which should be formatted especially. For example, **shr** is an infix operator like **mod** or **div**. It corresponds to bitwise shifting right.

```
format shr ≡ div
```

10. Cases. Following Knuth’s “T_EX: The Program” (§4), we will use **endcases** to pair with **case**. The “default case” will be **othercases** (because **else** gets too confusing).

```
define othercases ≡ others: { default for cases not listed explicitly }
define endcases ≡ end { follows the default case in an extended case statement }
format othercases ≡ else
format endcases ≡ end
```

11. Debugging. There are conditional compiler directives for debugging purposes. Importantly, these *must* be printed to the source code when we invoke `TANGLE`.

```
define mdebug ≡ @{@&$IFDEF MDEBUG@}
define end_mdebug ≡ @{@&$ENDIF@}
format mdebug ≡ begin
format end_mdebug ≡ end
```

12. Actually, it may be useful just to have helper macros.

```
define if_def( # ) ≡ @{@&$IFDEF #@}
define if_not_def( # ) ≡ @{@&$IFNDEF #@}
define else_if_def( # ) ≡ @{@&$ELSEIF DEFINED( # )@}
define else_def ≡ @{@&$ELSE@}
define endif ≡ @{@&$ENDIF@}
define end_if ≡ endif
format if_def ≡ if
format if_not_def ≡ if
format else_if_def ≡ else
format else_def ≡ else
format endif ≡ end
format end_if ≡ end
```

13. Toggling IO Checking. Another compiler directive enables and disables IO checking

```
define disable_io_checking ≡ @{@&$I-@}
define enable_io_checking ≡ @{@&$I+@}
define without_io_checking( # ) ≡ disable_io_checking; #; enable_io_checking
```

14. Logging. There appears to be a *CHReport* logger introduced in `kernel/prephan.pas`, but its type is defined in `kernel/req_info.pas`.

15. References. I have inline citations to the literature, but there’s some references worth explicitly drawing the reader’s attention to (which may or may not make it to an inline citation):

I should also credit Wayne Sewell’s *Weaving a Program: Literate Programming in Web* (Van Nostrand Reinhold Computer, 1989) for discussing how to take a pre-existing PASCAL program and turn it into a `WEB`. Or, depending on the quality of writing in this literate program, it’s all his fault.

Section 0.1. MIZAR'S WORKFLOW

16. This section will give a brief overview of what Mizar “does” when we run it. The analogy to bear in mind is with a batch compiler: there’s parsing, some intermediate steps, then emits some output.

Just to give some rough estimates of where Mizar spends most of its time, there are four phases Mizar reports when checking an article:

- (1) Parser (transforms input into an abstract syntax tree, writes it to an XML file);
- (2) MSM (transforms the abstract syntax tree into an explicitly typed intermediate representation) — `base/first_identification.pas`, the *MSMAnalyzer* procedure; this will require transcribing `kernel/limits.pas` (which is mostly just a bunch of constant parameters);
- (3) Analyzer (performs type checking, tracks the goals, and other miscellaneous jobs) — the *Analyze* procedure in `kernel/analyzer.pas`; this requires transcribing kernel code (`lexicon.pas`, `inout.pas`, `iocorrel.pas`, `correl.pas`, `generato.pas`, `builtin.pas`, `justhan.pas`, `enums.pas`, `formats.pas`, `identify.pas`) and base code (`xmldict.pas`), approximately 19590 lines (16764 lines of code, the rest is whitespace and comments)
- (4) Checker (performs the proof checking for validity) — the *InferenceChecker* procedure in `kernel/checker.pas`. This requires transcribing kernel files (`checker.pas` `prechecker.pas` `equalizer.pas` `unifier.pas` `justhan.pas`), approximately 8191 lines of code.

Using numbers Mario Carneiro reported in his github repository, roughly 14/15 of Mizar’s runtime (as measured in CPU time) is spent on the Analyzer and Checker phases (among which, Mizar spends about 5 times longer in the Checker phase than the Analyzer phase). Parsing and MSM transforms the input into an intermediate representation used in the latter two phases. Mizar spends about 1/15 of its time here.

17. Accommodator. This will produce, among other outputs, the “.dct” file (and its XML counterpart, the “.dcx” file). The “.dct” file contains all the identifiers imported from other articles and reserved keywords for Mizar. The Tokeniser needs it to properly tokenise an article.

18. Parsing phase. We can look at `kernel/verfinit.pas` to find the parsing phase of the Mizar program is handled by the following lines of code:

```
InitPass(`Parser_␣`); FileExam(EnvFileName + `.dct`);
InitScanning(MizFileName + ArticleExt, EnvFileName); InitWSMizarArticle; Parse;
gFormatsColl.StoreFormats(EnvFileName + `.frx`); gFormatsColl.Done; FinishScanning;
Write_WSMizArticle(gWSTextProper, EnvFileName + `.wsx`);
```

Our goal is to examine these functions, and understand what is going on. We know *Parse* is defined in `base/parse.pas`, it populates the *gWSTextProper* global variable using `base/parseraddition.pas`, and *Write_WSMizArticle* is defined in `base/wsmarticle.pas`. The *Parse* function continuously invokes *ReadToken* (§886).

This phase will be responsible for generating a “.frx” (formats XML) and a “.wsx” (weakly strict Mizar XML) file.

Subsection 0.1.1. Map of Mizar

19. It will be useful to provide a summary of the files, to give the reader an idea where to find various things. We offer the following grouping of files. We will enumerate them by the chapter wherein the file is discussed.

20. System-dependent code.

- (1) `base/mizenv.pas` provides functions for manipulating strings and file I/O
- (2) `base/pcmizver.pas` contains the major and minor version for Mizar, and data about the build
- (3) `base/mconsole.pas` provides common functions for printing messages to the console and parsing command line optional arguments
- (4) `base/errhan.pas` contains the *Position* type, functions for reporting errors, writing them in particular files
- (5) `base/info.pas` for debugging purposes, logging to a `.inf` file
- (6) `base/monitor.pas` code for signal processing, reports errors, and when calamity strikes exit Mizar
- (7) `base/mtime.pas` uniform framework for timing things
- (8) `base/mstate.pas` code for reset the current position in an article and marking the time

21. Infrastructure for the rest of Mizar’s object-oriented code.

- (9) `base/numbers.pas` contains code for arbitrary-precision integers, rational numbers, and rational complex numbers
- (10) `base/mobjects.pas` contains the common data structures used in Mizar, things like dynamic arrays and the *MObject* base class;

22. XML infrastructure.

- (11) `base/xml_dict.pas` contains only constant parameters and enumerated types
- (12) `base/librenv.pas` code for accessing the `pre1/` subdirectories of the current article and of `$MIZFILES/` — this is only here because it defines the *MizFiles* global variable which stores the full path of the `$MIZFILES/` environmental variable, and *MizFiles* is needed in `xml_inout.pas`; [This *MizFiles* global variable should be refactored out to an earlier unit, because `librenv.pas` seems out of place here;]
- (13) `base/xml_parser.pas` provides an abstract syntax tree for XML and parses XML
- (14) `base/xml_inout.pas` handles reading from and writing to XML files, plus escaping strings, etc.

23. Tokenisation and other “intermediate file management”.

- (15) `base/dicthan.pas` loading “.voc” files, and transform them into “.vct” and XML “.vcx” files
- (16) `base/scanner.pas` the Tokeniser and Scanner are implemented here (the naming is a little confusing, the *Scanner* class is the Tokeniser, and the *Tokeniser* class is an “abstract Tokeniser” operating on an arbitrary input stream accessed by an abstract *GetPhrase* method); also note, if we want to extend Mizar to support UTF-8 character encoding instead of ASCII, then this is the file we would modify;
- (17) `base/_formats.pas` contains the data structures for “formats” (basically a (Identifier, Number of arguments to left, Number of arguments to right) triple) used for parsing expressions;

24. Abstract syntax tree class hierarchies.

- (18) `base/syntax.pas` provides “abstract” classes *Subexpression* and *Expression* for expressions, *Item* and *Block* for statements; the actual subclasses used by the parser are in the `parseraddition.pas` file;
- (19) `base/mscanner.pas` provides a number of important global variables for the parser, “.prf” file management, as well as the *gScanner* global variable for the parser;
- (20) `base/abstract_syntax.pas` provides the abstract syntax tree for terms, types, attributes, formulas, and “within expressions”;
- (21) `base/wsmarticle.pas` “weakly strict Mizar” is the name for the initial internal representation of Mizar, which has its own class hierarchy here, as well as writing a “weakly strict Mizar” article to an XML file and reading back from an XML file into a “weakly strict Mizar” abstract syntax tree;

25. Parser “proper”.

- (22) `base/pragmas.pas` for parsing pragmas like “`::$P-`”, and global variables related to them;
- (23) `base/parseraddition.pas` for subclasses of the syntax tree class hierarchy from `syntax.pas`, used for constructing a “weakly strict Mizar” AST when parsing
- (24) `base/parser.pas` for parsing a token stream into an abstract syntax tree

Section 0.2. LOG OF TODOS, BUGS, IMPROVEMENTS

26. I have a number of observations from transcribing Mizar into WEB. They're the last thing I have included in the introductory chapter.

27. Possible improvements.

- (1) In quicksort, picking the pivot is done by $P \leftarrow (Low + High)/2$, but it should be done by $P \leftarrow Low + ((High - Low)/2)$ to avoid overflow.
- (2) Actually, quicksort should delegate work to a different sorting algorithm when there is less than 10 items in the list. Sedgewick pointed this out in his PhD thesis. (If quicksort *were* a culprit for slowness, we could even hardcode sort networks for small lists.)
- (3) We should also determine the pivot by looking at the median value of $P = (3 * Low + High)/4$, $P2 \leftarrow (Low + High)/2$, $P3 \leftarrow (Low + 3 * High)/4$. This will improve the performance of quicksort.
- (4) In §234, *GCD* could be optimized to avoid calculating $Mul(i, i)$ in every loop iteration.
- (5) In §471, *MStringList.ObjectOf* has duplicate code.
- (6) It seems that parsing Mizar text, emitting XML, and parsing XML seem to contain a lot of code which could be autogenerated from a grammar (a hypothetical “.ebnf” file). This would avoid duplicate work.

28. Possible bugs. I have been working through the source code with the mindset of, “How can I possibly break this?” This has led me to identify a number of situations where things can “go badly”. But they are not all bugs (some are impossible to occur).

- (1) In §433, *MSortedCollection.IndexOf* returns -1 when duplicate entries are allowed. Since Mizar does not seem to enable duplicate entries, this bug would never have been experienced or caught.
- (2) In §687, I think *TXTStreamObj.Done* needs to close the associated file.
- (3) In §723, *TSymbol.Init* expects an *fInfinite* argument, but does not use it — shouldn’t it initialize $Infinite \leftarrow fInfinite$?
- (4) In §660, escaped quotation marks are not properly handled.
- (5) For *StreamObj* (§680), the constructors and destructors are not virtual which would impact *XMLOutStreamObj* (§693) — well, we just do duplicate work in *XMLOutStreamObj*’s constructors and destructors.
- (6) Shouldn’t *TokensCollection.InitTokens* (§754) invoke the inherited constructor?
- (7) Shouldn’t *MTokenObj.Init* (§762) invoke inherited constructors? At least to insulate itself from changes to any of its parent (or grandparent) classes?
- (8) The constructor *OutWSMizFileObj.OpenFileWithXSL* (§1195) expects the XML-stylesheet located at `"file:/'+'$MIZFILES+'/'wsmiz.xml"`, but that file is not present in Mizar.
- (9) In *extItemObj.FinishFunctorPattern* (§1503), the default case does not add a new format to the *gFormatsColl* dictionary.
- (10) In *CreateArgs* (§1573) in `parseraddition.pas`, when $aBase \leq 0$, this will set *TermNbr* to a negative number.
- (11) In the *Subexpression* class, there is duplicate code (§1577) — the *CompleteAttributeArguments* and *FinishAttributeArguments* are identical, but only the latter is consistent with the naming conventions for the Parser. Or (probably more likely) I am misunderstanding the naming conventions?
- (12) In *CompleteArgument* (§1713), we should also test that *fParenthCnt* is positive, shouldn’t we?
- (13) The *CreateSubexpression* method (§1671), for extended expression objects, may result in a memory leak when *gSubexpPtr* $\neq \mathbf{nil}$ — that is to say, if *KillSubexpression* has not been invoked prior to *CreateSubexpression*.
- (14) Misnamed variable: *gIdentifyEqLociList* should be *gIdentifyEqLociList* (i.e., “identify” should be “identify” — with a ‘t’). (This typo has been corrected in the literate presentation of the code.)
- (15) As discussed in (§1466), there is a mismatch between the documentation and the Parser when it comes to parsing loci declarations in a definition block. The `syntax.txt` file is more restrictive than the Parser, and should be updated to reflect the Parser.
- (16) The *gSuchThat* global variable is never used anywhere (§1472)
- (17) In *ATTSubexpression* (§1895), in the **else** block when the conditional $lAttrExp \vee (aExpKind = exAdjectiveCluster)$ is executed, $aExpKind = exAdjectiveCluster$ is never true (so there’s no need for it).

29. To do list. There are some things I should revisit, revise, and edit — specifically about this running commentary (*not* the Mizar source code).

- (1) [Missing transcription] I skipped over transcribing the *ItemName* and other constants from `wsmarticle.pas`, which I should probably include.
- (2) [Revise] The XML schema should use the `doc/mizar/xml/Mizar.rnc` schema snippets.
- (3) [Revise] Make an introduction to dynamic arrays as a data structure, just to standardize the terminology used. (Make sure I stick to the standardized terminology!) Including pictures may help...
- (4) [Revise] Review quicksort. I should prove that it works, too. (Has this been done in Mizar? `exchsort` seems to be the closest match.)
- (5) [Improve] Give a “big picture” summary of the architecture. For example, the most interesting routine in parsing Mizar, well, it’s all handled in *MTokenizer.SliceIt* (§772).
- (6) [Linting] Standardize the names of basic data types. PASCAL accepts *integer* as synonymous with *Integer*, but they give different index entries.
- (7) [Cosmetics] Check the typography is correct for the code
- (8) [Cosmetics] Create more `WEB` macros for conditional compilation
- (9) [Cosmetics] Would it help to include more UML class diagrams?
- (10) [Improve] It may be useful to use UML State diagrams to explain the parser — or it may be a huge distraction?

30. Formatting types. This is still a finicky aspect of `WEB`. Strings are a type in Free PASCAL, like *Boolean*.

Looking at Wirth’s book, he typesets a type in *italics* and lowercase — so we have *boolean* and not **boolean** or *Boolean* (or **Boolean** or **boolean** or...). Knuth’s “`TEX`: the program” follows this convention (using *integer*, *boolean*, *char*, etc.).

31. Using Twill (or not). Knuth invented Twill as a “hack” atop `WEAVE` to include “mini-indices” every couple pages. The problem I have with Twill is that it does not adequately index local variables (in the sense that: Knuth’s `TEX` is a giant monolithic program, and any **var** appearing in it is almost certainly a global variable — hence it makes sense to index *all* variables, since they are almost certainly global).

I *want* to use Twill, but it is designed specifically *for* Knuth. Consequently it is not terribly useful for our purposes. We would have to tailor it quite heavily, and I don’t have the energy or patience to do so.

32. Caution: Knuth takes advantage of `WEB` to use `snake_case` when naming things instead of Pascal’s idiomatic `PascalCase`. This probably greatly improves the readability of the code. We should probably think hard about using it.

When `WEAVE` extracts the PASCAL code, it will remove all underscores from the identifiers and capitalize all letters. So instead of “*screaming_run_on_case*” (which appears in the PDF), we will instead obtain “`SCREAMINGRUNONCASE`”, which... yeah, that’s a hot mess.

Section 0.3. REVIEW OF PASCAL

33. Following Wirth's *Systematic Programming: An Introduction* (Prentice-Hall, 1973; viz., Chapter 7), we can offer the following axiomatic semantics for most of PASCAL's statements.

Assignment statements:

$$\frac{}{\{P[w/v]\} v \leftarrow w \{P\}}$$

Compound statements:

$$\frac{\frac{\{P\} S_1 \{Q\} \quad \{Q\} S_2 \{R\}}{\{P\} S_1; S_2 \{R\}}}{\{P\} S_1; S_2 \{R\}}$$

Conditional statements:

$$\frac{\frac{\{P \wedge B\} S_1 \{Q\} \quad \{P \wedge \neg B\} S_2 \{Q\}}{\{P\} \text{ if } B \text{ then } S_1 \text{ else } S_2 \{Q\}}}{\{P\} \text{ if } B \text{ then } S_1 \text{ else } S_2 \{Q\}}$$

Simpler conditional statements:

$$\frac{\frac{\{P \wedge B\} S \{Q\} \quad \{P \wedge \neg B\} \implies \{Q\}}{\{P\} \text{ if } B \text{ then } S \{Q\}}}{\{P\} \text{ if } B \text{ then } S \{Q\}}$$

While statements:

$$\frac{\{P \wedge B\} S \{P\}}{\{P\} \text{ while } B \text{ do } S \{P \wedge \neg B\}}$$

Repeat statements:

$$\frac{\frac{\{P\} S \{Q\} \quad \{Q \wedge \neg B\} S \{Q\}}{\{P\} \text{ repeat } S \text{ until } B \{Q \wedge B\}}}{\{P\} \text{ repeat } S \text{ until } B \{Q \wedge B\}}$$

Selective statement (and $i = L_k$ for some k):

$$\frac{\{P \wedge (i = L_k)\} S_k \{Q\} \text{ for all } k = 1, \dots, n}{\{P\} \text{ case } i \text{ of} \\ L_1: S_1; \\ L_2: S_2; \\ \vdots \\ L_n: S_n; \\ \text{end; } \{Q\}}$$

When there is no k such that $i = L_k$, the **case** statement is the same as evaluating i .

We can weaken the precondition:

$$\frac{P_1 \implies P_2, \quad \{P_2\} S \{Q\}}{\{P_1\} S \{Q\}}$$

We can strengthen the postcondition (Equation (11.16), page 85, of Wirth's book):

$$\frac{Q_2 \implies Q_1, \quad \{P\} S \{Q_2\}}{\{P\} S \{Q_1\}}$$

These rules are justified as *a priori* valid in Chapter 5 of Wirth.

For-loops may be derived as:

$$\frac{\frac{\{ (V = a) \wedge P \} S \{ Q(a) \} \quad \{ Q(pred(x)) \} S \{ Q(x) \} \text{ for all } a < x \leq b}{\{ (a \leq b) \wedge P \} \text{ for } V \leftarrow a \text{ to } b \text{ do } S \{ Q(b) \}}}{\{ (a > b) \wedge P \} \text{ for } V \leftarrow a \text{ to } b \text{ do } S \{ P \}}$$

34. The *exit* procedure may be invoked in a procedure or function, and it terminates the function or procedure. It roughly corresponds to C's **return** statement.

File 1

Mizar environment

35. We want to abstract away all the system dependent code, and provide a set of common functions Mizar will use to interact with the file system. This will include some helper functions for trimming whitespace from a String.

```

< mizenv.pas 35 > ≡
  < GNU License 4 >
unit mizenv;
  interface
    < interface for mizenv.pas 36 >
  implementation
    < Modules used by mizenv.pas 37 >
    < implementation of mizenv.pas 38 >
end .

```

36. There are a few common “global variables” used by the rest of Mizar. Specifically, Mizar will be processing a file (“article”). The file may be an absolute path (e.g., /path/to/article.miz), a relative path (../article.miz), or just the filename (article.miz). In any event, we will want to refer to the filename (article.miz) as well as what Mizar calls the “article ID” (in this case, “ARTICLE” — the filename without the file extension, transformed to all capital letters).

Modern programmers may find discomfort working with global variables (and for good reason!). We remind such readers that it was common practice, until very recently, for compilers and interpreters to use global variables to describe the state of the compiler (or interpreter). We will freely refer to these global variables as “state variables”, since that captures the role they play more accurately.

```

< interface for mizenv.pas 36 > ≡
var MizFileName: string; { the article “article.miz” }
    ArticleName: string; { the “article” without the “.miz” }
    ArticleID: string; { “ARTICLE” in screaming snake case }
    ArticleExt: string; { “.miz” from the MizFileName }
    EnvFileName: string; { the file name given to Mizar as a command-line argument }
procedure SetStringLength(var aString : string; aLength : integer);

```

See also sections 39, 41, 43, 47, 49, 51, 53, 55, 57, 59, 61, 63, and 65.

This code is used in section 35.

37. The implementation begins with various “uses”. Depending on the PASCAL compiler and operating system, different libraries need to be loaded.

```

< Modules used by mizenv.pas 37 > ≡
uses { compiler dependent imports }
    if_def (DELPHI) IOUtils, SysUtils, windows, endif
    if_def (FPC) dos, SysUtils, endif
    mconsole; { the only Mizar module mizenv.pas uses }

```

This code is used in section 35.

38. As far as setting the String length, this is a straightforward implementation. When the desired *aLength* is less than the actual length of *aString*, simply delete all characters after *aLength*.

Otherwise, *aString* has fewer characters than desired, so we pad it on the right with however many spaces until the String is as long as *aLength*.

⟨implementation of mizenv.pas 38⟩ ≡

```
procedure SetStringLength(var aString : string; aLength : integer);
  var I, L: integer;
  begin L ← length(aString);
  if aLength ≤ L then Delete(aString, aLength + 1, L - aLength)
  else for I ← 1 to aLength - L do aString ← aString + '␣';
  end;
```

See also sections 40, 42, 44, 48, 50, 52, 54, 56, 58, 60, 62, 64, 66, 70, 72, 73, 74, 75, 77, and 78.

This code is used in section 35.

39. Trimming whitespace. Trimming the left String will repeatedly delete any leading whitespace, until the String is empty or has no leading whitespace.

Similarly, trimming the right String will repeatedly delete the *last* character until it is no longer whitespace (or until the String becomes empty).

Remember, PASCAL is call-by-value, so the string arguments are copied when these functions are invoked. We are mutating the copy of the argument, and returning them to the user.

⟨interface for mizenv.pas 36⟩ +≡

```
function TrimStringLeft(aString : string): string;
function TrimStringRight(aString : string): string;
```

40. ⟨implementation of mizenv.pas 38⟩ +≡

```
function TrimStringLeft(aString : string): string;
  begin while (length(aString) > 0) ∧ (aString[1] = '␣') do Delete(aString, 1, 1);
  TrimStringLeft ← aString;
  end;

function TrimStringRight(aString : string): string;
  begin while (length(aString) > 0) ∧ (aString[length(aString)] = '␣') do
    Delete(aString, length(aString), 1);
  TrimStringRight ← aString;
  end;
```

41. Trimming a String amounts to trimming it on the left and right.

⟨interface for mizenv.pas 36⟩ +≡

```
function TrimString(const aString: string): string;
```

42. ⟨implementation of mizenv.pas 38⟩ +≡

```
function TrimString(const aString: string): string;
  begin TrimString ← TrimStringRight(TrimStringLeft(aString));
  end;
```

43. Uppercase and lowercase strings. We have a few more String manipulation functions for changing case, and turning an integer into a String.

⟨interface for mizenv.pas 36⟩ +≡

```
function UpperCase(const aStr: string): string;
function MizLoCase(aChar : char): char;
function LowerCase(const aStr: string): string;
function IntToStr(aInt : integer): string;
```

44. Now, uppercase strings are obtained by uppercasing each character.

⟨implementation of mizenv.pas 38⟩ +≡

```
function UpperCase(const aStr: string): string;
  var k: integer; { index ranging over aStr }
      lStr: string; { the uppercased String being built and returned }
  begin lStr ← aStr;
  for k ← 1 to length(aStr) do lStr[k] ← UpCase(aStr[k]);
  UpperCase ← lStr;
end;
```

45. Lowercasing a String can be done by iteratively replacing each character with its lowercase version. This “lowercase a single character” function is precisely *MizLoCase*.

If the reader wished for a UTF-8 version of Mizar, then this function would require thinking very hard about how to generalize.

```
function MizLoCase(aChar : char): char;
  begin if aChar ∈ [‘A’ .. ‘Z’] then MizLoCase ← Chr(Ord(‘a’) + Ord(aChar) – Ord(‘A’))
  else MizLoCase ← aChar;
  end;

function LowerCase(const aStr: string): string;
  var i: integer; { index ranging over aStr’s length }
      lStr: String; { result being built up }
  begin lStr ← aStr;
  for i ← 1 to length(aStr) do lStr[i] ← MizLoCase(aStr[i]);
  LowerCase ← lStr;
end;
```

46. We also want a *function* to convert an integer to a String. PASCAL provides us with a *procedure*.

```
function IntToStr(aInt : integer): string;
  var lStr: string;
  begin Str(aInt, lStr); IntToStr ← lStr;
end;
```

47. **File name manipulation.** We will want to test if a file exists, or split a path (represented as a String) into a directory and a filename.

Testing if a file exists uses the Free Pascal’s primitive *FileExists* function.

Similarly, *EraseFile* is just relying on Free Pascal’s *SysUtils.DeleteFile* function.

⟨interface for mizenv.pas 36⟩ +≡

```
function MFileExists(const aFileName: string): Boolean;
procedure EraseFile(const aFileName: string);
```

48. ⟨implementation of mizenv.pas 38⟩ +≡

```
function MFileExists(const aFileName: String): Boolean;
  begin MFileExists ← FileExists(aFileName); end;

procedure EraseFile(const aFileName: String);
  begin SysUtils.DeleteFile(aFileName); end;
```

49. We will destructively rename a file. If a file with the name already exists, we delete it. CAUTION: This function is not used anywhere, and it appears to be buggy (the file is deleted and then renamed, which begs the question—why is it deleted?).

```
<interface for mizenv.pas 36> +≡
procedure RenameFile(const aName1, aName2: string);
```

```
50. <implementation of mizenv.pas 38> +≡
procedure RenameFile(const aName1, aName2: String); { unused }
  begin if MFileExists(aName1) then EraseFile(aName2);
    SysUtils.RenameFile(aName1, aName2);
  end;
```

51. Again, relying on Free Pascal's *FileAge* function, which returns the modification time of the file. CAUTION: this will return a signed 32-bit integer, which will run into problems after 03:14:07 UTC on 19 January 2038 because that's $2^{31} - 1$ seconds since the UNIX epoch.

```
<interface for mizenv.pas 36> +≡
function GetFileTime(aFileName : string): Longint;
```

```
52. <implementation of mizenv.pas 38> +≡
function GetFileTime(aFileName : String): Longint;
  begin GetFileTime ← FileAge(aFileName); end;
```

53. Split a file name into components, namely (1) the directory, (2) the file name, (3) its extension. For example, */path/to/my/file.exe* will be split into */path/to/my/*, *file*, and *exe*.

This implementation depends on the compiler used (Delphi or Free Pascal).

```
<interface for mizenv.pas 36> +≡
procedure SplitFileName (const aFileName: string;
  var aDir, aName, aExt: string ) ;
```

```
54. <implementation of mizenv.pas 38> +≡
procedure SplitFileName (const aFileName: string; { input }
  var aDir, aName, aExt: string ) ; { output }

  begin
  if_def (FPC)
    aDir ← SysUtils.ExtractFilePath(aFileName);
    aName ← SysUtils.ExtractFileName(aFileName);
    aExt ← SysUtils.ExtractFileExt(aFileName);
  endif
  if_def (DELPHI)
    aDir ← TPath.GetDirectoryName(aFileName);
    aName ← TPath.GetFileName(aFileName);
    aExt ← TPath.GetExtension(aFileName);
  endif
  end ;
```

55. “Truncating a directory” means “throw away the directory part of the path” so we end up with just a filename and the file extension.

```
<interface for mizenv.pas 36> +≡
function TruncDir(const aFileName: string): string;
```

56. \langle implementation of mizenv.pas 38 $\rangle + \equiv$

```
function TruncDir(const aFileName: string): string;
  var Dir, lName, Ext: string;
  begin SplitFileName(aFileName, Dir, lName, Ext); TruncDir  $\leftarrow$  lName + Ext;
  end;
```

57. “Truncating the extension” means throwing away the extension part of a path.

\langle interface for mizenv.pas 36 $\rangle + \equiv$

```
function TruncExt(const aFileName: string): string;
```

58. \langle implementation of mizenv.pas 38 $\rangle + \equiv$

```
function TruncExt(const aFileName: string): string;
  var Dir, lName, Ext: string;
  begin SplitFileName(aFileName, Dir, lName, Ext); TruncExt  $\leftarrow$  Dir + lName;
  end;
```

59. Extracting the file directory will return *just* the directory part of a path.

\langle interface for mizenv.pas 36 $\rangle + \equiv$

```
function ExtractFileDir(const aFileName: string): string;
```

60. \langle implementation of mizenv.pas 38 $\rangle + \equiv$

```
function ExtractFileDir(const aFileName: string): string;
  var Dir, lName, Ext: string;
  begin SplitFileName(aFileName, Dir, lName, Ext); ExtractFileDir  $\leftarrow$  Dir;
  end;
```

61. Extracting the file name will throw away both the directory and extension. For example, extracting the file name from the path “/path/to/file.ext” gives us “file”. Extracting the file extension from the same path gives us “.ext”.

\langle interface for mizenv.pas 36 $\rangle + \equiv$

```
function ExtractFileName(const aFileName: string): string;
```

```
function ExtractFileExt(const aFileName: string): string;
```

62. \langle implementation of mizenv.pas 38 $\rangle + \equiv$

```
function ExtractFileName(const aFileName: string): string;
  var Dir, lName, Ext: string;
  begin SplitFileName(aFileName, Dir, lName, Ext); ExtractFileName  $\leftarrow$  lName;
  end;
```

```
function ExtractFileExt(const aFileName: string): string;
```

```
  var Dir, lName, Ext: string;
```

```
  begin SplitFileName(aFileName, Dir, lName, Ext); ExtractFileExt  $\leftarrow$  Ext;
```

```
  end;
```

63. Changing a file name’s extension. See:

freepascal.org/docs-html/rtl/sysutils/changefileext.html

Note this does not actually change the filename in the file system, it just changes it *as a string*.

\langle interface for mizenv.pas 36 $\rangle + \equiv$

```
function ChangeFileExt(const aFileName, aFileExt: string): string;
```

64. \langle implementation of mizenv.pas 38 $\rangle + \equiv$
function *ChangeFileExt*(**const** *aFileName*, *aFileExt*: *string*): *string*;
begin *ChangeFileExt* \leftarrow *SysUtils.ChangeFileExt*(*aFileName*, *aFileExt*); **end**;

65. **Environment variables.** Getting an environment variable. The reader wishing to learn more about what POSIX says about environmental variables may consult the POSIX standard, Volume 1 Chapter 8:

pubs.opengroup.org/onlinepubs/9799919799/basedefs/V1_chap08.html

The Free PASCAL compiler handles this situation far friendlier than Delphi.

\langle interface for mizenv.pas 36 $\rangle + \equiv$
function *GetEnvStr*(*aEnvName* : *string*): *string*;

66. \langle implementation of mizenv.pas 38 $\rangle + \equiv$
function *GetEnvStr*(*aEnvName* : *string*): *string*;
if_def (*FPC*)
begin *GetEnvStr* \leftarrow *GetEnv*(*aEnvname*); **end**;
endif
if_def (*DELPHI*) \langle Get environment variable, Delphi-compatible mode 67 \rangle
endif

67. The Delphi-compatible version of obtaining an environment variable is rather involved: copy the string, make it null terminated, look up the value.

\langle Get environment variable, Delphi-compatible mode 67 $\rangle \equiv$
const *cchBuffer* = 255;
var *lName*, *lpszTempPath*: **array** [0 .. *cchBuffer*] **of** *char*;
i: *integer*; *lStr*: *string*;
begin \langle Copy the variable name as a null-terminated string 68 \rangle ;
if *GetEnvironmentVariable*(*lName*, *lpszTempPath*, *cchBuffer*) > 0 **then**
begin \langle Copy environment variable's value into *lStr* until we find null character 69 \rangle ;
end;
GetEnvStr \leftarrow *lStr*;
end;

This code is used in section 66.

68. \langle Copy the variable name as a null-terminated string 68 $\rangle \equiv$
lStr \leftarrow '';
for *i* \leftarrow 1 **to** *length*(*aEnvname*) **do** *lName*[*i* - 1] \leftarrow *aEnvname*[*i*];
lName[*length*(*aEnvname*)] \leftarrow #0

This code is used in section 67.

69. \langle Copy environment variable's value into *lStr* until we find null character 69 $\rangle \equiv$
for *i* \leftarrow 0 **to** *cchBuffer* **do**
begin **if** *lpszTempPath*[*i*] = #0 **then** *break*;
lStr \leftarrow *lStr* + *lpszTempPath*[*i*];
end

This code is used in section 67.

70. Common printing routines. Examining a file amounts to testing if we can open the file. We close the file after opening it (because we don't want to actually want to do anything with it).

We should tweak how WEB formats a file to make it resemble the other types, rather than leave it as a “type operator” like **array** (which is the default due to Knuth).

format *file* \equiv *integer* ;

(implementation of mizenv.pas 38) \equiv

```
procedure FileExam(const aFileName: string);
var Source: file; { the file named aFileName }
    I: byte; { IOResult from trying to open the file }
begin if aFileName = '' then (Halt: we can't open the file 71);
    FileMode  $\leftarrow$  0; Assign(Source, aFileName); without_io_checking(Reset(Source)); I  $\leftarrow$  IOResult;
if I  $\neq$  0 then DrawIOResult(aFileName, I); { (§122) }
    close(Source); FileMode  $\leftarrow$  2;
end;
```

71. (Halt: we can't open the file 71) \equiv

```
begin DrawMessage('Can't open ' + aFileName + '.miz', ''); { (§118) } halt(1);
end
```

This code is used in section 70.

72. The user provides a file to Mizar as the command line argument. This typically looks like a relative path “**tex/article**” without any file extension. Before even trying to open “**tex/article.miz**”, or any of the related autogenerated intermediate files, we should test the file exists.

This procedure will notify the user if the file does not exist, otherwise it is silent.

Again, *DrawMessage* comes from *mconsole.pas* (§118).

(implementation of mizenv.pas 38) \equiv

```
procedure EnvFileExam(const aFileExt: string);
begin if  $\neg$ MFileExists(EnvFileName + aFileExt) then
    begin DrawMessage('Can't open ' + EnvFileName + aFileExt + '.miz', ''); Halt(1);
    end;
end;
```

73. This function isn't used anywhere in Mizar. It's also misnamed: we are not “getting” the file name, we are *updating* the file extension if the file lacks one. A better name might be “populate missing file extension”. Further, this does not test if the *Nr* command line argument is actually a file name or not, which is a possible source of bugs.

Remember, the *ParamCount* is PASCAL's way of counting the command-line parameters passed to the program.

(implementation of mizenv.pas 38) \equiv

```
procedure GetFileName(ParamNr : byte; DefaultExt : string; var aFileName : string);
var lFileExt: string;
begin if ParamNr  $\leq$  ParamCount then
    begin aFileName  $\leftarrow$  ParamStr(ParamNr); lFileExt  $\leftarrow$  ExtractFileExt(aFileName);
    if lFileExt = '' then aFileName  $\leftarrow$  ChangeFileExt(aFileName, DefaultExt);
    exit
    end;
    aFileName  $\leftarrow$  '';
end;
```

74. This procedure will take the Nr command line argument. If it lacks a file extension, then it will append the *DefaultExt* to it. At the end, this will populate *aFileName* and *aFileExt* based on the command line. It's only used in the *GetMizFileName* procedure, and nowhere else in Mizar.

The *ParamStr*(Nr) returns the Nr^{th} parameter as a String (it's a PASCAL primitive).

```

⟨implementation of mizenv.pas 38⟩ +≡
procedure GetFileExtName(Nr : byte; DefaultExt : string; var aFileName : string; var aFileExt : string);
begin if Nr ≤ ParamCount then
  begin aFileName ← ParamStr(Nr); aFileExt ← ExtractFileExt(aFileName);
  if aFileExt = '' then aFileExt ← DefaultExt
  else aFileName ← ChangeFileExt(aFileName, '');
  exit
  end;
aFileName ← ''; aFileExt ← '';
end;

```

75. Populate the state variables using the command-line arguments. We need to find the first command-line argument which resembles a Mizar article name. Note that Mizar articles have several files associated with it (the article's contents in a .miz file, the vocabulary in a .voc file, and XML related intermediate representation in .xml files, as well as .evl files).

Command line flags prefixed with a dash ("-") will not be interpreted as the name of a Mizar article.

If there are multiple articles passed to Mizar as command-line arguments, then this function finds the first one (and uses it to populate the state variables).

A possible bug: if there are multiple files passed to Mizar and the first file passed is not a ".miz" file, then Mizar will halt as a failure instead of continuing looking for the needle in the haystack.

```

⟨implementation of mizenv.pas 38⟩ +≡
procedure GetMizFileName(aFileExt : String);
var i : integer;
begin MizFileName ← ''; ArticleName ← ''; ArticleExt ← ''; EnvFileName ← '';
for i ← 1 to ParamCount do
  if ParamStr(i)[1] ≠ '-' then
    begin MizFileName ← ParamStr(i); GetFileExtName(i, aFileExt, MizFileName, ArticleExt);
    ArticleName ← ExtractFileName(MizFileName); ArticleID ← UpperCase(ArticleName);
    if ¬IsMMLIdentifier(ArticleName) then ⟨Halt: invalid article name 76⟩;
    EnvFileName ← MizFileName; exit;
    end;
end;

```

```

76. ⟨Halt: invalid article name 76⟩ ≡
  begin DrawMessage('Only_letters, numbers and _ allowed in Mizar file names', ''); halt(1);
  end

```

This code is used in section 75.

77. We will provide a standard way to populate the global variables.

```

⟨implementation of mizenv.pas 38⟩ +≡
procedure GetArticleName;
begin GetMizFileName('.miz');
end;

```

$$\langle \text{implementation of mizenv.pas } 38 \rangle + \equiv$$

79. The valid characters which can appear in a Mizar article name (an “MML Identifier”) are uppercase Latin letters (A-Z), lowercase Latin letters (a-z), decimal digits (0-9), and underscores (_).

[illegible]

File 2

PC Mizar Version

80. This is used to track the version of Mizar.

```

< pcmizver.pas 80 > ≡
  < GNU License 4 >
unit pcmizver;
interface
  const < Constants for pcmizver.pas 81 >
    < Public functions for pcmizver.pas 84 >
implementation
  < Implementation for pcmizver.pas 85 >
end .

```

81. Note the slight variant of terminology compared to semantic versioning “Major.Minor.Patch”, Mizar uses “Release.Version.Variant”. This appears to be just a minor difference in vocabulary.

```

< Constants for pcmizver.pas 81 > ≡
  PCMizarReleaseNbr = 8;
  PCMizarVersionNbr = 1;
  PCMizarVariantNbr = 14;

```

See also sections 82 and 83.

This code is used in section 80.

82. The current year could probably be determined from the PASCAL system utilities, but it is hardcoded to 2025. The *CurrentYear* is only used in one procedure in this module, so we could easily replace it with (the possibly non-portable) *FormatDateTime*(‘YYYY’, *Now*).

```

< Constants for pcmizver.pas 81 > +≡
  CurrentYear = 2025;

```

83. The directory separator for the file system supports Windows and UNIX-like file systems. So Classic macOS and QNX users would have to request this changed.

Note: it might be wiser, for Free PASCAL users, to use the *DirectorySeparator* constant from the *system* unit.

```

< Constants for pcmizver.pas 81 > +≡
  @{@&$IFDEF WIN32@}DirSeparator = ‘\’;
  @{@&$ELSE@}DirSeparator = ‘/’;
  @{@&$ENDIF@}

```

84. There are only four functions provided by this module.

⟨Public functions for `pcmizver.pas` 84⟩ ≡

```
function PCMizarVersionStr: string;
function VersionStr: string;
function PlatformNameStr: string;
function Copyright: string;
```

This code is used in section 80.

85. Their implementation is relatively straightforward: just print the appropriate constants to the screen.

⟨Implementation for `pcmizver.pas` 85⟩ ≡

```
function Copyright: string;
  var s: string;
  begin Str(CurrentYear, s);
  Copyright ← 'Copyright(c)1990-' + s + ' Association of Mizar Users';
end;
```

See also sections 86, 87, and 88.

This code is used in section 80.

86. ⟨Implementation for `pcmizver.pas` 85⟩ +≡

```
function VersionStr: string;
  var lRel, lVer, lVar: string[2]; lStr: string;
  begin Str(PCMizarReleaseNbr, lRel); Str(PCMizarVersionNbr, lVer); Str(PCMizarVariantNbr, lVar);
  if length(lVar) = 1 then lVar ← '0' + lVar;
  @{&&$IFDEF VERALPHA@} lStr ← '-alpha';
  @{&&$ELSE@} lStr ← '';
  @{&&$ENDIF@}
  VersionStr ← lRel + '.' + lVer + '.' + lVar + lStr;
end;
```

87. There are a number of platforms supported, a surprisingly large number. If we were to support more platforms (other BSDs, BeOS, GNU Hurd, etc.), then we would need to update this function. To see what platforms are predefined for FreePascal, consult:

- https://wiki.freepascal.org/Platform_defines

Ostensibly, we could extend the platform name string to display “generic UNIX” (and even “generic BSD”), as well as “generic Windows”.

⟨Implementation for `pcmizver.pas` 85⟩ +≡

```
function PlatformNameStr: string;
  var lStr: string;
  begin lStr ← '';
  if_def (WIN32) lStr ← lStr + 'Win32'; end_if
  if_def (LINUX) lStr ← lStr + 'Linux'; end_if
  if_def (SOLARIS) lStr ← lStr + 'Solaris'; end_if
  if_def (FREEBSD) lStr ← lStr + 'FreeBSD'; end_if
  if_def (DARWIN) lStr ← lStr + 'Darwin'; end_if
  if_def (FPC) lStr ← lStr + '/FPC'; end_if
  if_def (DELPHI) lStr ← lStr + '/Delphi'; end_if
  PlatformNameStr ← lStr;
end ;
```

88. The last function in the `pcmizver.pas` file provides a string for the Mizar version.

⟨Implementation for `pcmizver.pas` 85⟩ +≡

```
function PCMizarVersionStr: string;  
  begin PCMizarVersionStr ← 'Mizar_Ver.' + VersionStr;  
  end;
```

File 3

Mizar Console

89. The Mizar Console unit is used for interacting with the command line. Specifically, this module will be used for printing error messages, reporting progress, and parsing command-line arguments for configuration options.

```

< mconsole.pas 89 > ≡
  < GNU License 4 >
unit mconsole;
  interface < Report results to command line 108 >
    < Constants for common error messages reported to console 124 >
    < Interface for accommodator command line options 92 >
    < Interface for MakeEnv command line options 102 >
    < Interface for transfer-specific command line options 106 >
    < Interface for other command line options 93 >
  implementation
    < Import units for mconsole.pas 90 >
    < Implementation for mconsole.pas 96 >
end

```

90. We import two modules, *pcmizver* and *mizenv*,

```

< Import units for mconsole.pas 90 > ≡
uses pcmizver, mizenv;

```

This code is used in section 89.

91. We want to have a method which allows us to flag an error (*fErrNbr*) on a given line of the article being processed. But the user may request Mizar to silence these messages. We can facilitate this by having a *DisplayLine* procedure constant.

```

< DisplayLine global constant 91 > ≡
const DisplayLine: procedure (fLine, fErrNbr : integer) = NoDisplayLine;

```

This code is used in section 108.

Section 3.1. PARSING COMMAND-LINE ARGUMENTS

92. Now, we have accommodator specific options.

```

⟨Interface for accommodator command line options 92⟩ ≡
  { Accommodator specific options: }
var SignatureProcessing, { unused }
      TheoremListsProcessing, { unused }
      SchemeListsProcessing, { unused }
      InsertHiddenFiles, { Include HIDDEN automatically? }
      FormatsProcessing: Boolean;
var { Registrations-related configuration for Accommodator }
      ClustersProcessing, IdentifyProcessing, ReductionProcessing, PropertiesProcessing: Boolean;
var { The environ-specifical Accommodator options }
      VocabulariesProcessing, { Accommodator will run ProcessVocabularies }
      NotationsProcessing, { Accommodator processes notations directive }
      ConstructorsProcessing, { Will the Accommodator determine which constructor to use for identifier? }
      DefinitionsProcessing, EqualitiesProcessing, ExpansionsProcessing, { Definition environs }
      TheoremsProcessing, SchemesProcessing: Boolean; { unused variables }

```

See also sections 95 and 99.

This code is used in section 89.

93. Among the state variables introduced in the **mconsole** unit, there is one for handling **SIGINT**, **SIGQUIT**, and **SIGTERM** signals. [[The other UNIX signals should probably be supported, as well.]]

```

⟨Interface for other command line options 93⟩ ≡
  { Other options: }
var CtrlCPressed: Boolean = false; { SIGINT, SIGQUIT, or SIGTERM signal received? }
      LongLines: Boolean = false; { Allow lines longer than 80 characters }
      QuietMode: Boolean = false; { Don't print anything to the console? }
      StopOnError: Boolean = false;
      FinishingPass: Boolean = false; ParserOnly: Boolean = false; { No analyzing or checking }
      AnalyzerOnly: Boolean = false; { Analyze, but no parsing or checking }
      CheckerOnly: Boolean = false; { Check, but do not re-analyze or re-parse }
      SwitchOffUnifier: Boolean = false;
      AxiomsAllowed: Boolean = false;

```

See also section 104.

This code is used in section 89.

94. The implementation begins by initializing the Accommodator specific options. The default situation is every configuration option is *true* except for the unused variables *TheoremListsProcessing* and *SchemeListsProcessing* (both are *false*).

95. ⟨Interface for accommodator command line options 92⟩ +≡
procedure *InitAccOptions*;

96. \langle Implementation for `mconsole.pas` 96 $\rangle \equiv$

```
procedure InitAccOptions;
  begin InsertHiddenFiles  $\leftarrow$  true; VocabulariesProcessing  $\leftarrow$  true; FormatsProcessing  $\leftarrow$  true;
  NotationsProcessing  $\leftarrow$  true; SignatureProcessing  $\leftarrow$  true; ConstructorsProcessing  $\leftarrow$  true;
  ClustersProcessing  $\leftarrow$  true; IdentifyProcessing  $\leftarrow$  true; ReductionProcessing  $\leftarrow$  true;
  PropertiesProcessing  $\leftarrow$  true; DefinitionsProcessing  $\leftarrow$  true; EqualitiesProcessing  $\leftarrow$  true;
  ExpansionsProcessing  $\leftarrow$  true; TheoremsProcessing  $\leftarrow$  true; SchemesProcessing  $\leftarrow$  true;
  TheoremListsProcessing  $\leftarrow$  false; SchemeListsProcessing  $\leftarrow$  false;
  end;
```

See also sections 98, 100, 103, 105, 107, 109, 111, 113, 114, 116, 119, 121, 123, and 126.

This code is used in sections 89 and 117.

97. Similarly, we want to be able to *reset* the configuration for the accommodator make everything false. The motivation is that we want to enable only certain specific flags, and it's faster to set everything to *false* and then manually toggle the flags we want.

This is a private helper function for other things in the `mconsole`.

98. \langle Implementation for `mconsole.pas` 96 $\rangle + \equiv$

```
procedure ResetAccOptions;
  begin InsertHiddenFiles  $\leftarrow$  true; VocabulariesProcessing  $\leftarrow$  false; FormatsProcessing  $\leftarrow$  false;
  NotationsProcessing  $\leftarrow$  false; SignatureProcessing  $\leftarrow$  false; ConstructorsProcessing  $\leftarrow$  false;
  ClustersProcessing  $\leftarrow$  false; IdentifyProcessing  $\leftarrow$  false; ReductionProcessing  $\leftarrow$  false;
  PropertiesProcessing  $\leftarrow$  false; DefinitionsProcessing  $\leftarrow$  false; EqualitiesProcessing  $\leftarrow$  false;
  ExpansionsProcessing  $\leftarrow$  false; TheoremsProcessing  $\leftarrow$  false; SchemesProcessing  $\leftarrow$  false;
  TheoremListsProcessing  $\leftarrow$  false; SchemeListsProcessing  $\leftarrow$  false;
  end;
```

99. **Accommodator options.** We will get options for the accommodator passed in from the command line. Broadly, these are:

- `-v` resets the accommodator options, and then toggles *VocabulariesProcessing* to true
- `-f`, `-p` resets the accommodator options, and then toggles *VocabulariesProcessing* to true (so far like `-v`), and then toggles *FormatsProcessing* to true.
- `-P` resets the accommodator options, and then toggles *VocabulariesProcessing* to true (so far like `-v`), and then toggles *FormatsProcessing* to true (so far like `-f` and `-p`), then toggles *TheoremListsProcessing* and *SchemeListsProcessing* to both be true.
- `-e` will do everything `-f` does, and then toggles *ConstructorsProcessing*, *SignatureProcessing*, *ClustersProcessing*, and *NotationsProcessing* to all be true.
- `-h` will set *InsertHiddenFalse* to false (presumably preventing Mizar from loading the “hidden” article, i.e., the primitive notions of “object”, “<>”, “in”, and “strict” will not be loaded).
- `-l` will toggle *LongLines* to true (allowing lines with more than 80 characters)
- `-q` will toggle *QuietMode* to true
- `-s` will toggle *StopOnError* to true

Note this processes *all* command line options *in order*. So `-e -v` will produce the same results as `-v` alone.

\langle Interface for accommodator command line options 92 $\rangle + \equiv$

```
procedure GetAccOptions;
```

100. \langle Implementation for `mconsole.pas` 96 $\rangle + \equiv$

```

procedure GetAccOptions;
  var i, j: integer;
  begin InitAccOptions;
  for j  $\leftarrow$  1 to ParamCount do
    if ParamStr(j)[1] = '-' then
      for i  $\leftarrow$  2 to length(ParamStr(j)) do
        case ParamStr(j)[i] of
          'v': begin ResetAccOptions; VocabulariesProcessing  $\leftarrow$  true
            end;
          'f', 'p': begin ResetAccOptions; VocabulariesProcessing  $\leftarrow$  true; FormatsProcessing  $\leftarrow$  true;
            end;
          'P': begin ResetAccOptions; VocabulariesProcessing  $\leftarrow$  true; FormatsProcessing  $\leftarrow$  true;
              TheoremListsProcessing  $\leftarrow$  true; SchemeListsProcessing  $\leftarrow$  true;
            end;
          'e': begin ResetAccOptions; VocabulariesProcessing  $\leftarrow$  true; FormatsProcessing  $\leftarrow$  true;
              ConstructorsProcessing  $\leftarrow$  true; SignatureProcessing  $\leftarrow$  true; ClustersProcessing  $\leftarrow$  true;
              NotationsProcessing  $\leftarrow$  true;
            end;
          'h': begin InsertHiddenFiles  $\leftarrow$  false; end;
          'l': LongLines  $\leftarrow$  true;
          'q': QuietMode  $\leftarrow$  true;
          's': StopOnError  $\leftarrow$  true;
        endcases;
      end;
  end;

```

101. Similarly, we have *MakeEnv* specific options parsed from the command line flags.

102. \langle Interface for *MakeEnv* command line options 102 $\rangle \equiv$

{ *MakeEnv* specific options: }

var *Accommodation*: *Boolean* = *false*; *NewAccom*: *Boolean* = *false*;

procedure *GetMEOptions*;

This code is used in section 89.

103. \langle Implementation for `mconsole.pas` 96 $\rangle + \equiv$

```

procedure GetMEOptions;
  var i, j: integer;
  begin for j  $\leftarrow$  1 to ParamCount do
    if ParamStr(j)[1] = '-' then
      for i  $\leftarrow$  2 to length(ParamStr(j)) do
        case ParamStr(j)[i] of
          'n': NewAccom  $\leftarrow$  true;
          'a': Accommodation  $\leftarrow$  true;
          'l': LongLines  $\leftarrow$  true;
          'q': QuietMode  $\leftarrow$  true;
          's': StopOnError  $\leftarrow$  true;
        endcases;
      end;
  end;

```

104. The “other” options.

Notably, there is a feature to allow axioms, which is completely undocumented (and probably for good reason!). The user may automatically enable axioms by placing them all in “.axm” files.

⟨Interface for other command line options 93⟩ +≡
procedure *GetOptions*;

105. ⟨Implementation for mconsole.pas 96⟩ +≡
procedure *GetOptions*;

```

var i, j: integer;
begin for j ← 1 to ParamCount do
  if ParamStr(j)[1] = '-' then
    for i ← 2 to length(ParamStr(j)) do
      case ParamStr(j)[i] of
        'q': QuietMode ← true;
        'p': ParserOnly ← true;
        'a': AnalyzerOnly ← true;
        'c': CheckerOnly ← true;
        'l': LongLines ← true;
        's': StopOnError ← true;
        'u': SwitchOffUnifier ← true;
        'x': AxiomsAllowed ← true;
      othercases break;
    endcases;
  if ArticleExt = '.axm' then AxiomsAllowed ← true;
end;
```

106. Transfer specific options.

⟨Interface for transfer-specific command line options 106⟩ ≡

{ Transfer specific options: }

var *PublicLibr*: Boolean; { use “pre1/⟨Article-name⟩/” subdirectory? }

procedure *GetTransfOptions*;

This code is used in section 89.

107. ⟨Implementation for mconsole.pas 96⟩ +≡

procedure *GetTransfOptions*;

```

var lOption: string;
begin PublicLibr ← false;
if ParamCount ≥ 2 then
  begin lOption ← ParamStr(2);
    if (length(lOption) = 2) ∧ (lOption[1] ∈ [ '/', '- ']) then PublicLibr ← UpCase(lOption[2]) = 'P';
  end
end;
```

Section 3.2. REPORTING RESULTS TO THE CONSOLE

108. We have a number of functions useful for “drawing”, i.e., reporting progress and results (and so on).

```

⟨ Report results to command line 108 ⟩ ≡
procedure InitDisplayLine(const aComment: string);
procedure NoDisplayLine(fLine, fErrNbr : integer);
⟨ DisplayLine global constant 91 ⟩

```

See also sections 110, 112, 115, 117, 118, 120, 122, and 125.

This code is used in section 89.

109. The *gComment* is used only within this module. Mizar stores the name of the pass (parser, MSM, analyzer, checker) in *gComment*, which is used in a helper function to print the progress to the console.

```

⟨ Implementation for mconsole.pas 96 ⟩ +≡
var gComment: string = ``; { The pass currently being run }
    disable_io_checking;
procedure NoDisplayLine(fLine, fErrNbr : integer);
    begin end;
procedure InitDisplayLine(const aComment: string);
    begin gComment ← aComment; WriteLn; write(aComment); DisplayLine ← DisplayLineInCurPos
    end;

```

```

110. ⟨ Report results to command line 108 ⟩ +≡
procedure DrawMizarScreen(const aApplicationName: string);
procedure DrawArticleName(const fName: string);
procedure DrawStr(const aStr: string);
procedure FinishDrawing;

```

```

111. ⟨ Implementation for mconsole.pas 96 ⟩ +≡
procedure DrawStr(const aStr: string);
    begin write(aStr) end;
procedure FinishDrawing;
    begin WriteLn;
    end;
procedure DrawTPass(const fPassName: string);
    begin write(fPassName) end;
procedure DrawMizarScreen(const aApplicationName: string);
    begin WriteLn(aApplicationName, ` , □ `, PCMizarVersionStr, ` □ (`, PlatformNameStr, ` ) `);
    WriteLn(Copyright);
    end;

```

112. The *Noise* parameter rings the bell three times (the ↑G is Caret notation “Ctrl+G”, which is ASCII code 10 BEL). For non-Windows systems, this will write three BEL characters to the standard output stream. Windows will do nothing.

```

⟨ Report results to command line 108 ⟩ +≡
procedure EmptyParameterList;
procedure Noise;

```

113. \langle Implementation for mconsole.pas 96 $\rangle + \equiv$

```

procedure Noise;
  begin
    if_not_def (WIN32) write( $\uparrow G \uparrow G \uparrow G$ ); endif ;
  end ;
procedure EmptyParameterList;
  begin Noise; WriteLn; WriteLn(`****_Empty_Parameter_List_?_****`); halt(2);
end;

```

114. When the user asks Mizar to verify an article, Mizar will begin by writing to the standard output stream “Processing: \langle Article name \rangle ”.

\langle Implementation for mconsole.pas 96 $\rangle + \equiv$

```

procedure DrawArticleName(const fName: string);
  begin WriteLn(`Processing:_`, fName); end;

```

115. \langle Report results to command line 108 $\rangle + \equiv$

```

procedure DrawPass(const aName: string);
procedure DrawTime(const aTime: string);
procedure DrawVerifierExit(const aTime: string);

```

116. \langle Implementation for mconsole.pas 96 $\rangle + \equiv$

```

procedure DrawPass(const aName: string);
  begin WriteLn; write(aName); end;
procedure DrawTime(const aTime: string);
  begin write(aTime); end;
procedure DrawVerifierExit(const aTime: string);
  begin WriteLn; WriteLn(`Time_of_mizaring:`, aTime);
  end;

```

117. On non-Windows machines, $\uparrow M$ is used in *write* to add a carriage return. Windows machines will require #13 instead. This is because $\uparrow M$ is “Ctrl+M” which has ASCII code 77-64=13 (see, it’s the same as #13).

\langle Report results to command line 108 $\rangle + \equiv$

```

procedure DisplayLineInCurPos(fLine, fErrNbr : integer);  $\langle$  Implementation for mconsole.pas 96  $\rangle =$ 
  procedure DisplayLineInCurPos(fLine, fErrNbr : integer);
    begin if ( $\neg$ CtrlCPressed)  $\wedge$  ( $\neg$ QuietMode) then
      begin write( $\uparrow M + gComment + \_ \_$ , fLine : 4);
      if fErrNbr > 0 then write( $\_ \_ * \_$ , fErrNbr);
      write( $\_ \_$ );
      end;
    if FinishingPass then
      begin write( $\_ \_$ , fLine : 4);
      if fErrNbr > 0 then write( $\_ \_ * \_$ , fErrNbr);
      write( $\_ \_$ );
      end;
    end;

```

118. When Mizar needs to notify the user that a critical error has occurred, *DrawMessage* will be used for communicating it. By “critical error”, I mean things like Mizar cannot open the file, or there was a stack overflow, or the hard drive exploded.

⟨Report results to command line 108⟩ +≡

```
procedure DrawMessage(const Msg1, Msg2: string);
```

119. ⟨Implementation for *mconsole.pas* 96⟩ +≡

```
procedure DrawMessage(const Msg1, Msg2: string);
  var Lh: byte;
  begin Noise; WriteLn; write('***_ ', Msg1); Lh ← length(Msg1);
  if length(Msg2) > Lh then Lh ← length(Msg2);
  if Lh > length(Msg1) then write('_ ': Lh - length(Msg1));
  WriteLn('_*** ');
  if Msg2 ≠ '' then
    begin write('***_ ', Msg2);
    if Lh > length(Msg2) then write('_ ': Lh - length(Msg2));
    WriteLn('_*** ');
    end;
  end;
```

120. The *monitor.pas* file uses *BugInProcessor* when reporting errors. It's a logging function for severe situations.

⟨Report results to command line 108⟩ +≡

```
procedure BugInProcessor;
```

121. ⟨Implementation for *mconsole.pas* 96⟩ +≡

```
procedure BugInProcessor;
  begin DrawMessage('Internal_Error', ''); end;
```

122. When *reset* (or *rewrite*) fails, Mizar will cease. We should specifically report the situation to the user, because they can address the situation whereas we cannot.

⟨Report results to command line 108⟩ +≡

```
procedure DrawIOResult(const FileName: string; I: byte);
```

123. ⟨Implementation for *mconsole.pas* 96⟩ +≡

```
procedure DrawIOResult(const FileName: string; I: byte);
  begin if I ∈ [2 .. 6, 12, 100] then
    begin if I = 12 then I ← 7
    else if I = 100 then I ← 8;
    DrawMessage(ErrMsg[I], 'Can''t_open_' + FileName + '_ ');
    end
  else DrawMessage('Can''t_open_' + FileName + '_ ', '');
  halt(1);
  end;
```

124. We also have a constant for error messages commonly encountered.

⟨ Constants for common error messages reported to console 124 ⟩ ≡

```
const ErrMsg: array [1..6] of string[20] =
  (
    'File_not_found',
    'Path_not_found',
    'Too_many_open_files',
    'Disk_read_error',
    'Disk_write_error');
```

This code is used in section 89.

125. ⟨ Report results to command line 108 ⟩ +≡

```
procedure DrawErrorsMsg(aErrorNbr : integer);
```

126. ⟨ Implementation for mconsole.pas 96 ⟩ +≡

```
procedure DrawErrorsMSg(aErrorNbr : integer);
```

```
begin if aErrorNbr > 0 then
```

```
begin WriteLn;
```

```
if aErrorNbr = 1 then WriteLn('***_1_error_detected')
```

```
else WriteLn('***_', aErrorNbr, '_errors_detected');
```

```
end;
```

```
end;
```

File 4

Error handling

127. There are a few common error reporting routines bundled together. We should recall Borland PASCAL’s *RunError* method stops the execution of the program and generates a run-time error. The other primitive PASCAL function worth remembering is *Halt* which takes an error exit code, halts the program, and returns control to the calling program. For PASCAL specific error codes, consult:

<https://wiki.freepascal.org/RunError>

```

⟨errhan.pas 127⟩ ≡
  ⟨GNU License 4⟩
unit errhan;
  interface
    ⟨Interface for errhan.pas 128⟩
  implementation
    uses mconsole, mizenv;
    ⟨Implementation for errhan.pas 131⟩
  end ;

```

128. We have a few custom types and internal variables describing the state of the Mizar error handler.

The *Position* type is especially important for the Parser, which will store the metadata in the abstract syntax tree. The starchy reader may wish to consult the POSIX Standard’s [definition](#) (3.75 of Volume I) for “column position” which states, “Column positions are numbered starting from 1.” Coincidentally, this would imply Mizar cannot properly parse files longer than $2^{31} - 1$ columns wide (or $2^{63} - 1$ columns wide for 64-bit computers).

```

⟨Interface for errhan.pas 128⟩ ≡
type Position = ⟨Declare Position as record 129⟩;
  ErrorReport = procedure (Pos : Position; ErrNr : integer);
const ZeroPos: Position = (Line : 0; Col : 0);
var CurPos: Position; { current position }
    ErrorNbr: integer; { current error number }
    PutError: ErrorReport = nil; { reporter for errors }
    RTErrCode: integer = 0; { runtime error code }
    OverflowError: boolean = false; { overflow error? They’re horrible, treat accordingly }

```

See also sections [130](#), [132](#), [134](#), [139](#), [141](#), [143](#), [145](#), [147](#), and [149](#).

This code is used in section [127](#).

129. Position is just a pair of integers recording the line and offset (“column”).

```

⟨Declare Position as record 129⟩ ≡
  record Line, Col: integer
  end

```

This code is used in section [128](#).

130. The implementation begins as we would expect/hope. If we have a *preferred* error reporter already present in *PutError*, then we just use it. If we have toggled *StopOnError* to true, then we should end the program here (with a message).

If we want to report an error at the *CurrPos* (current position), then we have a helper function do that for us.

The *Error* and *ErrImm* procedures are both used in the parser.

⟨Interface for **errhan.pas 128**⟩ +≡

procedure *Error*(*Pos* : *Position*; *ErrNr* : *integer*);

procedure *ErrImm*(*ErrNr* : *integer*);

131. ⟨Implementation for **errhan.pas 131**⟩ ≡

procedure *Error*(*Pos* : *Position*; *ErrNr* : *integer*);

begin *inc*(*ErrorNbr*);

if @*PutError* ≠ **nil** **then** *PutError*(*Pos*, *ErrNr*);

if *StopOnError* **then**

begin *DrawMessage*(‘Stopped on first error’, ‘’); *Halt*(1); **end**;

end;

procedure *ErrImm*(*ErrNr* : *integer*);

begin *Error*(*CurPos*, *ErrNr*);

end;

See also sections 133, 135, 140, 142, 144, 146, 148, and 150.

This code is used in section 127.

132. We also can write errors to a file. This requires keeping track of the file (dubbed *Errors*) and whether it has been opened or not (in the Boolean condition *OpenedErrors*).

Note this takes advantage of **with** to destructure *Pos* into a *Line* and *Col* for us.

⟨Interface for **errhan.pas 128**⟩ +≡

procedure *WriteError*(*Pos* : *Position*; *ErrNr* : *integer*);

133. ⟨Implementation for **errhan.pas 131**⟩ +≡

var *Errors*: *text*; { file name for errors file }

OpenedErrors: *boolean* = *false*; { have we opened it yet? }

procedure *WriteError*(*Pos* : *Position*; *ErrNr* : *integer*);

begin **if** ¬*OpenedErrors* **then** *RunTimeError*(2001);

with *Pos* **do** *WriteLn*(*Errors*, *Line*, ‘_’, *Col*, ‘_’, *ErrNr*);

end;

134. Opening an errors file. We can open an errors file, which will reset the *ErrorNbr* counter to zero and re-initialize *CurPos* to line 1 and column 1.

When *PutError* is **nil**, we initialize it to be *WriteError*.

⟨Interface for **errhan.pas 128**⟩ +≡

procedure *OpenErrors*(*FileName* : *string*);

135. \langle Implementation for `errhan.pas` 131 $\rangle + \equiv$

```
procedure OpenErrors(FileName : string);
  begin if ExtractFileExt(FileName) = `` then FileName  $\leftarrow$  FileName + `.err`;
  Assign(Errors, FileName);
  without_io_checking(Rewrite(Errors)); { Open the FileName }
   $\langle$  If cannot open the FileName, report an error and halt 136  $\rangle$ ;
   $\langle$  Initialize errhan.pas state variables 137  $\rangle$ ;
   $\langle$  Set current position to first line, first column 138  $\rangle$ ;
  if @PutError = nil then PutError  $\leftarrow$  WriteError;
end;
```

136. \langle If cannot open the *FileName*, report an error and halt 136 $\rangle \equiv$

```
if IOResult  $\neq$  0 then
  begin DrawMessage(Can't open errors file + FileName + for writing, ``); halt(1);
end
```

This code is used in section 135.

137. \langle Initialize `errhan.pas` state variables 137 $\rangle \equiv$

```
OpenedErrors  $\leftarrow$  true; ErrorNbr  $\leftarrow$  0
```

This code is used in sections 135 and 140.

138. \langle Set current position to first line, first column 138 $\rangle \equiv$

```
with CurPos do
  begin Line  $\leftarrow$  1; Col  $\leftarrow$  1
end
```

This code is used in sections 135, 140, and 187.

139. Appending errors to the errors file. This isn't used anywhere in Mizar. It may be instructive for the reader to compare this to *OpenErrors*.

\langle Interface for `errhan.pas` 128 $\rangle + \equiv$

```
procedure AppendErrors(FileName : string);
```

140. \langle Implementation for `errhan.pas` 131 $\rangle + \equiv$

```
procedure AppendErrors(FileName : string); { unused }
  begin if ExtractFileExt(FileName) = `` then FileName  $\leftarrow$  FileName + `.err`;
  Assign(Errors, FileName);
   $\langle$  Initialize errhan.pas state variables 137  $\rangle$ ;
   $\langle$  Set current position to first line, first column 138  $\rangle$ ;
  without_io_checking(append(Errors));
  if IOResult  $\neq$  0 then Rewrite(Errors);
end;
```

141. We can also close the errors file and unset the *Errors* variable, “forgetting” where we logged the errors. This does not appear to be used anywhere in Mizar.

\langle Interface for `errhan.pas` 128 $\rangle + \equiv$

```
procedure EraseErrors;
```

142. \langle Implementation for `errhan.pas` 131 $\rangle + \equiv$

```
procedure EraseErrors;
  begin if OpenedErrors then
    begin OpenedErrors  $\leftarrow$  false; close(Errors); erase(Errors);
    end;
  end;
```

143. We can also just close the errors file. This is used in `monitor.pas`.

\langle Interface for `errhan.pas` 128 $\rangle + \equiv$

```
procedure CloseErrors;
```

144. \langle Implementation for `errhan.pas` 131 $\rangle + \equiv$

```
procedure CloseErrors;
  begin if OpenedErrors then
    begin OpenedErrors  $\leftarrow$  false; close(Errors);
    end;
  end;
```

145. Like I said, overflow errors are especially problematic. If/when they occur, we should just bail out immediately. Curiously, Free PASCAL uses the 202 error for stack overflow errors, and 203 for heap overflow errors. Mizar uses the 97 error code for overflow errors.

\langle Interface for `errhan.pas` 128 $\rangle + \equiv$

```
procedure OverflowError(ErrorCode : word);
```

146. \langle Implementation for `errhan.pas` 131 $\rangle + \equiv$

```
procedure OverflowError(ErrorCode : word);
  begin RTErrCode  $\leftarrow$  ErrorCode; OverflowError  $\leftarrow$  true; RunError(97);
  end;
```

147. We have an assertion utility to check if a *Cond* is *true*. When it is *false*, we should report a runtime error (i.e., update *RTErrCode* and invoke *RunError*(98)). Free PASCAL's *assert* function generates a 227 "Assertion failed error" error code upon failure.

\langle Interface for `errhan.pas` 128 $\rangle + \equiv$

```
procedure MizAssert(ErrorCode : word; Cond : Boolean);
```

148. \langle Implementation for `errhan.pas` 131 $\rangle + \equiv$

```
procedure MizAssert(ErrorCode : word; Cond : Boolean);
  begin if  $\neg$ Cond then
    begin RTErrCode  $\leftarrow$  ErrorCode; RunError(98);
    end;
  end;
```

149. Last, we have a catchall for runtime errors encountered.

\langle Interface for `errhan.pas` 128 $\rangle + \equiv$

```
procedure RunTimeError(ErrorCode : word);
```

150. \langle Implementation for `errhan.pas` 131 $\rangle + \equiv$

```
procedure RunTimeError(ErrorCode : word);
  begin RTErrCode  $\leftarrow$  ErrorCode; RunError(99);
  end;
```

File 5

Info file handling

151. I don't think this is actually used anywhere, but I am including it for completeness.

```

⟨ info.pas 151 ⟩ ≡
  ⟨ GNU License 4 ⟩
unit info;
  interface uses errhan;
  var InfoFile: text;

  procedure InfoChar(C : char);
  procedure InfoInt(I : integer);
  procedure InfoWord(C : char; I : integer);
  procedure InfoNewLine;
  procedure InfoString(S : string);
  procedure InfoPos(Pos : Position);
  procedure InfoCurPos;
  procedure OpenInfoFile;
  procedure CloseInfofile;

  implementation
  uses mizenv, mconsole;

  procedure InfoChar(C : char);
    begin write(InfoFile, C)
    end;

  procedure InfoInt(I : integer);
    begin write(InfoFile, I, '␣')
    end;

  procedure InfoWord(C : char; I : integer);
    begin write(InfoFile, C, I, '␣')
    end;

  procedure InfoNewLine;
    begin WriteLn(InfoFile)
    end;

  procedure InfoString(S : string);
    begin write(InfoFile, S)
    end;

  procedure InfoPos(Pos : Position);
    begin with Pos do write(InfoFile, Line, '␣', Col, '␣')
    end;

  procedure InfoCurPos;
    begin with CurPos do write(InfoFile, Line, '␣', Col, '␣')
    end;

```

152. There are a few helper functions which is more than “Write \langle data type \rangle to info file”.

```

var _InfoExitProc: pointer;
procedure InfoExitProc;
  begin CloseInfoFile; ExitProc  $\leftarrow$  _InfoExitProc;
  end;

procedure OpenInfoFile;
  begin Assign(InfoFile, MizFileName +  $\text{'\texttt{.inf'}}$ ); Rewrite(InfoFile);
  WriteLn(InfoFile,  $\text{'Mizared\_article:\_'\texttt{'}}$ , MizFileName,  $\text{'\texttt{'}}$ ); _InfoExitProc  $\leftarrow$  ExitProc;
  ExitProc  $\leftarrow$  @InfoExitProc;
  end;

procedure CloseInfofile;
  begin close(InfoFile)
  end;

end .

```

File 6

Monitor

153. There is only one single public-facing procedure in the `monitor.pas` file: *InitExitProc*. This just assigns the *_Halt_* function (defined in this module) to the *ExitProc* pointer global variable.

```

⟨ monitor.pas 153 ⟩ ≡
  ⟨ GNU License 4 ⟩
unit monitor;
interface
  procedure InitExitProc;
implementation
  ⟨ Units used by monitor.pas 154 ⟩;
  var _ExitProc: pointer; _IOResult: integer;
  ⟨ Implementation for monitor.pas 155 ⟩
end

```

154. The monitor is used for reporting errors, which is heavily system dependent. The modules used by it are...wonky. We need the *baseunix* unit for UNIX systems, and the *windows* unit for Windows-based systems.

```

⟨ Units used by monitor.pas 154 ⟩ ≡
uses
  @{@&$IFDEF FPC@}
    @{@&$IFDEF WIN32@}
      baseunix,
    @{@&$ENDIF@}
  @{@&$ENDIF@}
  mizenv, errhan, mconsole
  @{@&$IFDEF WIN32@} , windows @{@&$ENDIF@}
  mdebug , info end_mdebug

```

This code is used in section 153.

155. There are a few private helper functions in this module.

⟨Implementation for `monitor.pas` 155⟩ ≡

```

procedure _Halt_(ErrorCode : word);
begin IOResult ← IOResult; ErrorAddr ← nil;
if ErrorCode > 1 then
  case ErrorCode of
    2 .. 4: begin ErrImm(1000 + ErrorCode); DrawMessage('I/O_error', ErrMsg[ErrorCode]) end;
    5 .. 6: begin ErrImm(1000 + ErrorCode); BugInProcessor end;
    12: begin ErrImm(1000 + ErrorCode); BugInProcessor end;
    97, 98, 99: begin ErrImm(RTErrorCode); ⟨Handle runtime error cases for monitor.pas 156⟩
  end;
    100 .. 101: begin ErrImm(1000 + ErrorCode); DrawMessage('I/O_error', ErrMsg[ErrorCode - 95]);
  end;
    102 .. 106: begin ErrImm(1000 + ErrorCode); BugInProcessor end;
    150 .. 162: begin ErrImm(1000 + ErrorCode);
      DrawMessage('I/O_error', 'Critical_disk_error');
    end;
    200 .. 201: begin ErrImm(1000 + ErrorCode); BugInProcessor end;
    202: begin ErrImm(1000 + ErrorCode); DrawMessage('Stack_overflow_error', '') end;
    203, 204: begin ErrImm(1000 + ErrorCode); DrawMessage('Heap_overflow_error', '') end;
    208: begin ErrImm(1000 + ErrorCode); DrawMessage('Overlay_manager_not_installed', '') end;
    209: begin ErrImm(1000 + ErrorCode); DrawMessage('Overlay_file_read_error', '') end;
    210 .. 212: begin ErrImm(1000 + ErrorCode); BugInProcessor end;
    213: begin ErrImm(1000 + ErrorCode); DrawMessage('Collection_Index_out_of_range', '') end;
    214: begin ErrImm(1000 + ErrorCode); DrawMessage('Collection_overflow_error', '') end;
    215: begin ErrImm(1000 + ErrorCode); DrawMessage('Arithmetic_overflow_error', '') end;
    216: begin ErrImm(1000 + ErrorCode); DrawMessage('General_Protection_fault', '') end;
    217: begin ErrImm(1000 + ErrorCode); DrawMessage('Segmentation_fault', '') end;
    218 .. 254: begin ErrImm(1000 + ErrorCode); BugInProcessor end;
    255: ErrImm(1000 + ErrorCode);
  othercases begin ErrImm(ErrorCode);
    if OverflowError then DrawMessage('Mizar_parameter_overflow_error', '')
    else BugInProcessor
    end;
  endcases;
  CloseErrors; ExitProc ← _ExitProc;
if (ErrorCode = 0) ∧ (ErrorNbr ≠ 0) then Halt(1)
else Halt(ErrorCode);
end;

```

See also section 157.

This code is used in section 153.

156. $\langle \text{Handle runtime error cases for } \text{monitor.pas } 156 \rangle \equiv$

```

case RTErrorCode of
800,804: DrawMessage('Library_Corrupted', '');
857: DrawMessage('Connection_Fault', '');
      { 900..999: DrawMessage('Mizar parameter overflow: ' + IntToStr(RTErrorCode), ''); }
1255: DrawMessage('User_break', '');
othercases if OverflowError then
      DrawMessage('Mizar_parameter_overflow: ' + IntToStr(RTErrorCode), '')
else BugInProcessor
endcases;

```

This code is used in section 155.

157. The *MizExitProc* is a private “bail out” function.

$\langle \text{Implementation for } \text{monitor.pas } 155 \rangle + \equiv$

```

procedure MizExitProc;
begin
  @{@&$IFDEF IODEBUG@} ExitProc  $\leftarrow$  _ExitProc;
  @{@&$ELSE@} _Halt_(ExitCode);
  @{@&$ENDIF@}
end;

```

158. We use the *MizExitProc* to initialize the *ExitProc* pointer.

```

procedure InitExitProc;
begin ExitProc  $\leftarrow$  @MizExitProc
end;

```

159. **Initializing Control.** This is a *heavily* system dependent piece of code. There are two ways to implement it (one way for Windows, another way for everyone else). Once we’re done, we have to initialize the *_ExitProc* and invoke *InitCtrl*.

$\langle \text{Non-windows FreePascal implemenation for } \text{InitCtrl } 160 \rangle$

$\langle \text{Windows implemenation for } \text{InitCtrl } 161 \rangle$

```

begin _ExitProc  $\leftarrow$  ExitProc; InitCtrl;
end.

```

160. $\langle \text{Non-windows FreePascal implemenation for } \text{InitCtrl } 160 \rangle \equiv$

```

@{@&$IFDEF FPC@}  @{@&$IFNDEF WIN32@}
procedure CatchSignal(aSig : integer); cdecl;
begin
  case aSig of
    SIGINT, SIGQUIT, SIGTERM: begin CtrlCPressed  $\leftarrow$  true; RunTimeError(1255); end;
  endcases;
end;
var NewSignal, OldSigInt: SignalHandler;
procedure InitCtrl;
begin NewSignal  $\leftarrow$  SignalHandler(@CatchSignal); OldSigInt  $\leftarrow$  fpSignal(SIGINT, NewSignal);
  OldSigInt  $\leftarrow$  fpSignal(SIGQUIT, NewSignal); OldSigInt  $\leftarrow$  fpSignal(SIGTERM, NewSignal);
end;
  @{@&$ENDIF@}@{@&$ENDIF@}

```

This code is used in section 159.

161. Microsoft breaks everything. This is a mess because of them.

```

⟨ Windows implemenation for InitCtrl 161 ⟩ ≡
  @{ @&$IFDEF WIN32 @}
    ⟨ Windows implemenation for CtrlSignal 164 ⟩
    @{ @&$IFDEF FPC @}

  @{ @&$IFDEF DELPHI @}
function CtrlSignal(aSignal : DWORD): BOOL; cdecl;
  @{ @&$ENDIF @}

```

This code is used in section 164.

File 7

Time utilities

167. We will want to report to the user how much time Mizar takes during various phases of execution. This is another heavily “system dependent” library.

```

<mtime.pas 167> ≡
  <GNU License 4>
unit mtime;
  interface
    <Interface for mtime.pas 172>
  implementation
    <Implementation for mtime.pas 168>
  end ;

```

168. The implementation begins with a rather *thorny* digression depending on which compiler we’re using.

```

<Implementation for mtime.pas 168> ≡
  <Timing utilities uses for Delphi 169>
  <Timing utilities uses for FreePascal 170>

```

See also sections 171, 173, 175, 177, 178, 180, and 184.

This code is used in section 167.

169. Delphi simply requires us to introduce a constant for milliseconds.

```

<Timing utilities uses for Delphi 169> ≡
  @{@&$IFDEF DELPHI@}
  uses windows;
const cmSecs = 1000;
  @{@&$ENDIF@}

```

This code is used in section 168.

170. FreePascal requires a bit more work, alas. We can use the *GetTime* procedure to populate the hours, minutes, seconds, and hundredths of a second. American readers forgetful of the metric system should know that $0.01\text{ s} = 10\text{ ms}$ (one hundredth of a second is ten milliseconds).

Note: the *wMilliseconds* parameter is misnamed, it does not measure in units of milliseconds but centiseconds.

```

< Timing utilities uses for FreePascal 170 > ≡
  @{@&$IFDEF FPC@}
    uses dos;
const cmSecs = 100; { = 100 centiseconds per 1 second }
type TSystemTime =
  record wHour: word;
    wMinute: word;
    wSecond: word;
    wMilliseconds: word;
  end;
procedure GetLocalTime(var aTime : TSystemTime);
  begin with aTime do GetTime(wHour, wMinute, wSecond, wMilliseconds);
  end;
  @{@&$ENDIF@}

```

This code is used in section 168.

171. Now we can happily plug along implementing the functions we need. This is slightly misnamed, the result will be *centiseconds* (hundredths of a second).

```

< Implementation for mtime.pas 168 > +≡
function SystemTimeToMiliSec(const fTime: TSystemTime): longint;
  begin SystemTimeToMiliSec ← fTime.wHour * (3600 * cmSecs) +
    fTime.wMinute * longint(60 * cmSecs) + fTime.wSecond * cmSecs + fTime.wMilliseconds;
  end;

```

172. Time since we “started the clock”. The result is stored in the variable *W*.

```

< Interface for mtime.pas 172 > ≡
procedure TimeMark(var W : longint);

```

See also sections 174, 176, 179, and 183.

This code is used in section 167.

```

173. < Implementation for mtime.pas 168 > +≡
procedure TimeMark(var W : longint);
  var SystemTime: TSystemTime;
  begin GetLocalTime(SystemTime); W ← SystemTimeToMiliSec(SystemTime);
  end;

```

174. When we have measured the time already *W* since the system started (in “milliseconds”), and we want to get the elapsed time *since we measured W*, then this function will accomplish the task. If *W* is greater than the lifetime of Mizar’s run, then clearly something has gone awry. Mizar assumes a day has passed (in that case).

Note that $86400 = 24 \times 60 \times 60$ is the number of minutes in one day.

```

< Interface for mtime.pas 172 > +≡
function ElapsedTime(W : longint): longint;

```

175. \langle Implementation for `mtime.pas 168` $\rangle + \equiv$

```
function ElapsedTime(W : longint): longint;
  var T: longint; SystemTime: TSystemTime;
  begin GetLocalTime(SystemTime); T  $\leftarrow$  SystemTimeToMiliSec(SystemTime) - W;
  if T < 0 then T  $\leftarrow$  86400 * cmSecs + T;
  ElapsedTime  $\leftarrow$  T;
end;
```

176. We can transform an interval of time (in “milliseconds”) into hours, minutes, seconds, a fractional amount of time.

\langle Interface for `mtime.pas 172` $\rangle + \equiv$

```
procedure MUnpackTime(W : longint; var H, M, S, F : word);
```

177. \langle Implementation for `mtime.pas 168` $\rangle + \equiv$

```
procedure MUnpackTime(W : longint; var H, M, S, F : word);
  begin H  $\leftarrow$  W div (3600 * cmSecs); M  $\leftarrow$  (W - H * 3600 * cmSecs) div (60 * cmSecs);
  S  $\leftarrow$  (W - H * 3600 * cmSecs - M * 60 * cmSecs) div cmSecs;
  F  $\leftarrow$  W - H * 3600 * cmSecs - M * 60 * cmSecs - S * cmSecs;
end;
```

178. When reporting time, we want to pad the time by a zero. This is standard conventional stuff (e.g., I have an appointment at 11:01 AM, not 11:1 AM).

\langle Implementation for `mtime.pas 168` $\rangle + \equiv$

```
function LeadingZero(w : word): String;
  var lStr: String;
  begin Str(w : 0, lStr);
  if length(lStr) = 1 then lStr  $\leftarrow$  '0' + lStr;
  LeadingZero  $\leftarrow$  lStr;
end;
```

179. Reporting time transforms a time interval (measured in milliseconds) into a human readable String.

\langle Interface for `mtime.pas 172` $\rangle + \equiv$

```
function ReportTime(W : longint): String;
```

180. \langle Implementation for `mtime.pas 168` $\rangle + \equiv$

```
function ReportTime(W : longint): String;
  var H, M, S, F: word; lTimeStr: String;
  begin MUnpackTime(ElapsedTime(W), H, M, S, F);  $\langle$  Round to nearest second 181  $\rangle$ ;
  if H  $\neq$  0 then  $\langle$  Report hours and minutes 182  $\rangle$ 
  else Str(M : 2, lTimeStr); {report minutes}
  ReportTime  $\leftarrow$  lTimeStr + ':' + LeadingZero(S); {...and seconds}
end;
```

181. \langle Round to nearest second 181 $\rangle \equiv$

```
if F  $\geq$  (cmSecs div 2) then inc(S)
```

This code is used in section 180.

182. \langle Report hours and minutes 182 $\rangle \equiv$

```
begin Str(H, lTimeStr); lTimeStr  $\leftarrow$  lTimeStr + ':' + LeadingZero(M)
end
```

This code is used in section 180.

183. We also have one global variable tracking the start time of Mizar. Every time Mizar starts up, it will “mark the time” (i.e., assign to the *gStartTime* global variable the current time).

⟨Interface for `mtime.pas` 172⟩ +≡
var *gStartTime*: *longint*;

184. When we run the program, we should mark the time.

⟨Implementation for `mtime.pas` 168⟩ +≡
 begin *TimeMark*(*gStartTime*);
 end.

File 8

Mizar internal state

185. As far as *processing* an article, Mizar works like a “batch compiler” and works in multiple “passes”. We will want to report on each “pass”, informing the user how long it took or how many errors were encountered.

```

⟨ mstate.pas 185 ⟩ ≡
  ⟨ GNU License 4 ⟩
unit mstate;
  interface
    ⟨ Interface for mstate.pas 186 ⟩
  implementation
    uses mizenv, pcmizver, monitor, errhan, mconsole, mtime
    mdebug , info end_mdebug ;
    ⟨ Implementation for mstate.pas 187 ⟩
  end

```

186. We have a local (well, “module”-wide) variable *PassTime* to “start the clock” for measuring how long a pass took.

The implementation amounts to, well, these four functions. We have a couple “private” functions to help us: *MError* and *MizarExitProc*.

```

⟨ Interface for mstate.pas 186 ⟩ ≡
procedure InitPass(const aPassName: string);

```

See also sections 188, 192, and 196.

This code is used in section 185.

```

187. ⟨ Implementation for mstate.pas 187 ⟩ ≡
var PassTime: longint;
procedure InitPass(const aPassName: string);
begin ⟨ Set current position to first line, first column 138 ⟩;
  InitDisplayLine(aPassName); { (§109) }
  TimeMark(PassTime);
end;

```

See also sections 189, 191, 193, and 197.

This code is used in section 185.

```

188. ⟨ Interface for mstate.pas 186 ⟩ +≡
procedure FinishPass;

```

```

189. ⟨ Implementation for mstate.pas 187 ⟩ +≡
procedure FinishPass;
begin FinishingPass ← true;
if QuietMode then DisplayLine(CurPos.Line, ErrorNbr);
  FinishingPass ← false; DrawTime(⌈⌋ + ReportTime(PassTime));
end;

```

190. We also have *MizarExitProc* as a private “helper” function.

191. \langle Implementation for *mstate.pas* 187 $\rangle + \equiv$

```
var _ExitProc: pointer;
procedure MizarExitProc;
  begin ExitProc  $\leftarrow$  _ExitProc;
  disable_io_checking;
  if IOResult  $\neq$  0 then ;
  if  $\neg$ StopOnError then DisplayLine(CurPos.Line, ErrorNbr);
  PutError  $\leftarrow$  WriteError; { (§132) }
  DrawVerifierExit(ReportTime(gStartTime));
  enable_io_checking;
end;
```

192. \langle Interface for *mstate.pas* 186 $\rangle + \equiv$

```
procedure InitProcessing(const aProgName, aExt: String);
```

193. \langle Implementation for *mstate.pas* 187 $\rangle + \equiv$

```
procedure MError(Pos : Position; ErrNr : integer);
  begin WriteError(Pos, ErrNr); { (§132) }
  DisplayLine(CurPos.Line, ErrorNbr); { (§91) }
end;

procedure InitProcessing(const aProgName, aExt: string);
  begin DrawMizarScreen(aProgName);
  if ParamCount < 1 then EmptyParameterList;
   $\langle$  Parse the command-line arguments for article name and options 194  $\rangle$ ;
   $\langle$  Initialize the ExitProc 195  $\rangle$ ;
  PutError  $\leftarrow$  MError; OpenErrors(MizFileName);
  mdebug OpenInfoFile; end_mdebug
end;
```

194. \langle Parse the command-line arguments for article name and options 194 $\rangle \equiv$

```
GetArticleName; GetEnvironName; DrawArticleName(MizFileName + aExt); GetOptions
```

This code is used in section 193.

195. \langle Initialize the ExitProc 195 $\rangle \equiv$

```
InitExitProc; FileExam(MizFileName + aExt); _ExitProc  $\leftarrow$  ExitProc; ExitProc  $\leftarrow$  @MizarExitProc
```

This code is used in section 193.

196. At the end, we should report the number of errors (if any were encountered).

\langle Interface for *mstate.pas* 186 $\rangle + \equiv$

```
procedure ProcessingEnding;
```

197. \langle Implementation for *mstate.pas* 187 $\rangle + \equiv$

```
procedure ProcessingEnding;
  begin if ErrorNbr > 0 then
    begin DrawErrorsMsg(ErrorNbr); FinishDrawing;
    end;
  end;
```

File 9

Arbitrary precision arithmetic

198. Specifically, arbitrary precision arithmetic on *integers* and *rational complex* numbers. integers are represented as Strings of digits.

Note:

- (1) The naming convention dictates all functions suffixed with *_XXX* presuppose the arguments are positive.
- (2) Also there are *no checks* whether the parameters contain only digits (and an optional sign “-”).
- (3) Further, *DEBUGNUM* is a conditional variable that can be used (with *DEBUG*) for testing. We can easily turn this into a macro.

(I think we could even introduce a macro $\text{log_num}(\#) \equiv \text{debug_num}(\text{WriteLn}(\#)) \dots$)

define *debug_num*(#) \equiv @{@&\$IFDEF DEBUGNUM@} #@{@&\$ENDIF@}

< numbers.pas 198 > \equiv

< GNU License 4 >

unit *numbers*;

end .

Section 9.1. ARBITRARY-PRECISION INTEGERS

199. We will use “schoolbook arithmetic”, representing an arbitrary precision integer as a string of digits, possibly leading with an optional sign. We will “normalize” the representation by the constraint: if the leading digit is zero, then the number is zero. So we will need to trim superfluous leading zeros.

We will also adopt the convention that the empty string is a synonym for zero.

200. If we are given single character string consisting of zero or the empty string, then we are done.

If we are given anything else, we find the first index (from the left) of a nonzero character. Then we create a copy of the substring starting from the first nonzero digit to the rest of the string.

This will break if given a string of zeroes like $a = \text{'00'}$, in the sense that the empty string will be returned.

⟨Trim leading zeros from arbitrary-precision integers 200⟩ \equiv

```
function trimlz( $a : \text{string}$ ):  $\text{string}$ ;
  var  $i$ :  $\text{integer}$ ;
  begin if ( $a = \text{'0'}$ )  $\vee$  ( $a = \text{''}$ ) then  $\text{trimlz} \leftarrow a$ 
  else begin  $i \leftarrow 0$ ;
    repeat  $i \leftarrow i + 1$ ;
      if  $a[i] \neq \text{'0'}$  then break;
    until  $i = \text{length}(a)$ ;
     $\text{trimlz} \leftarrow \text{copy}(a, i, \text{length}(a))$ ;
  end;
end;
```

This code is used in section 198.

201. First, we check if a starts with “−0”. If so, replace a with 0. Then we do the same thing with b .

We invoke *trimlz* on a and store the result in $a1$. If $a1 \neq a$, then we update $a \leftarrow a1$.

Then we do likewise on b .

⟨Check if arbitrary-precision integers are zero 201⟩ \equiv

```
procedure checkzero(var  $a, b : \text{string}$ );
  var  $a1, b1 : \text{string}$ ;
  begin ⟨Convert “−0” into zero 202⟩;
  ⟨Trim leading zeros from numerator and denominator 203⟩;
  end;
```

This code is used in section 198.

202. ⟨Convert “−0” into zero 202⟩ \equiv

```
if  $\text{copy}(a, 1, 2) = \text{'-0'}$  then
  begin  $\text{debug\_num}(\text{WriteLn}(\text{infofile}, \text{'a=-0'}))$ ;
   $a \leftarrow \text{'0'}$ ;
  end;
if  $\text{copy}(b, 1, 2) = \text{'-0'}$  then
  begin  $\text{debug\_num}(\text{WriteLn}(\text{infofile}, \text{'b=-0'}))$ ;
   $b \leftarrow \text{'0'}$ ;
  end
```

This code is used in section 201.

203. \langle Trim leading zeros from numerator and denominator 203 $\rangle \equiv$

```

a1  $\leftarrow$  trimlz(a);
if a1  $\neq$  a then
  begin debug_num(WriteLn(infofile, ^ZEROS1: ^, a));
  a  $\leftarrow$  a1;
  end;
b1  $\leftarrow$  trimlz(b);
if b1  $\neq$  b then
  begin debug_num(WriteLn(infofile, ^ZEROS2: ^, b));
  b  $\leftarrow$  b1;
  end

```

This code is used in section 201.

204. Since arbitrary precision numbers (as Strings) are negative if they begin with a leading “-” character, it is easy to obtain the absolute value (just delete the minus sign). This assumes there are “double negatives” like “--5”; the “absolute value” of “--5” would yield “-5”, which should be a bug.

\langle Basic arithmetic operations declarations 204 $\rangle \equiv$

function Abs(a : string): string;

See also sections 225, 232, 234, 236, 238, 243, 248, 250, 252, and 254.

This code is used in section 198.

205. \langle Absolute value for an arbitrary-precision number 205 $\rangle \equiv$

function Abs(a : string): string;

```

begin if length(a) > 0 then
  if a[1] = ^-^ then delete(a, 1, 1);
  Abs  $\leftarrow$  a;
end;

```

This code is used in section 198.

206. When checking $a \leq b$ for two non-negative integers, written as Strings (without leading zeros) you can check if the length of a is less than the length of b .

If the length of b is less than the length of a , then $b < a$.

When the length of the two Strings are equal, use lexicographic ordering to determine which is less.

\langle Test if one arbitrary-precision number is less than or equal to another 206 $\rangle \equiv$

function _leq(a, b : string): boolean; { compare two positive integers }

```

var i, x, y, z: integer;
begin debug_num(WriteLn(infofile, ^_leq(^, a, ^, ^, b, ^));
  checkzero(a, b);
  if length(a) < length(b) then _leq  $\leftarrow$  true
  else if length(a) > length(b) then _leq  $\leftarrow$  false
  else  $\langle$  Compare two positive integers with same number of digits 207  $\rangle$ ;
  end;

```

See also sections 208, 209, and 210.

This code is used in section 198.

207. $\langle \text{Compare two positive integers with same number of digits } 207 \rangle \equiv$

```

begin for  $i \leftarrow 1$  to  $\text{length}(a)$  do
  begin  $\text{val}(a[i], x, z); \text{val}(b[i], y, z);$ 
  if  $x > y$  then
    begin  $\_leq \leftarrow \text{false}; \text{exit};$ 
  end;
  if  $x < y$  then
    begin  $\_leq \leftarrow \text{true}; \text{exit};$ 
  end;
end;
 $\_leq \leftarrow \text{true};$ 
end

```

This code is used in section 206.

208. Now the *general* case is when a and b are arbitrary-precision *integers*. If a starts with a minus sign and b starts with a minus sign, then test if $a \geq b$.

When a does not start with a minus sign, but b *does* start with a minus sign, then we're done: $b < a$.

When neither a nor b starts with a minus sign, then we use $_leq(a, b)$ to determine the result.

$\langle \text{Test if one arbitrary-precision number is less than or equal to another } 206 \rangle + \equiv$

```

function  $\_leq(a, b : \text{string})$ : Boolean;
begin  $\text{debug\_num}(\text{WriteLn}(\text{infofile}, \text{'leq('}, a, \text{'}, \text{'}, b, \text{'})'}));$ 
 $\text{checkzero}(a, b);$ 
if  $a = b$  then  $\_leq \leftarrow \text{true}$ 
else begin if  $(a[1] = \text{'-'}) \wedge (b[1] \neq \text{'-'})$  then  $\_leq \leftarrow \text{true};$ 
  if  $(a[1] = \text{'-'}) \wedge (b[1] = \text{'-'})$  then  $\_leq \leftarrow \neg \_leq(\text{abs}(a), \text{abs}(b));$ 
  if  $(a[1] \neq \text{'-'}) \wedge (b[1] = \text{'-'})$  then  $\_leq \leftarrow \text{false};$ 
  if  $(a[1] \neq \text{'-'}) \wedge (b[1] \neq \text{'-'})$  then  $\_leq \leftarrow \_leq(a, b);$ 
end;
end;

```

209. Testing if $a \geq b$ is simply testing if $b \leq a$ after normalizing the Strings. Mizar implements this by $(a > b) \vee (a = b)$, since $\neg(a \leq b)$ is identical to $a > b$.

$\langle \text{Test if one arbitrary-precision number is less than or equal to another } 206 \rangle + \equiv$

```

function  $\_geq(a, b : \text{string})$ : Boolean;
begin  $\text{debug\_num}(\text{WriteLn}(\text{infofile}, \text{'geq('}, a, \text{'}, \text{'}, b, \text{'})'}));$ 
 $\text{checkzero}(a, b);$ 
 $\_geq \leftarrow (\neg \_leq(a, b)) \vee (a = b);$ 
end;

```

210. Similarly, we may check if $a < b$ by testing $a \neq b$ and $a \leq b$.

$\langle \text{Test if one arbitrary-precision number is less than or equal to another } 206 \rangle + \equiv$

```

function  $\_le(a, b : \text{string})$ : Boolean;
begin  $\text{debug\_num}(\text{WriteLn}(\text{infofile}, \text{'le('}, a, \text{'}, \text{'}, b, \text{'})'}));$ 
 $\text{checkzero}(a, b); \_le \leftarrow (a \neq b) \wedge (\_leq(a, b));$ 
end;

function  $\_gt(a, b : \text{string})$ : Boolean;
begin  $\text{debug\_num}(\text{WriteLn}(\text{infofile}, \text{'gt('}, a, \text{'}, \text{'}, b, \text{'})'}));$ 
 $\_gt \leftarrow \neg \_le(a, b);$ 
end;

```

Subsection 9.1.1. Arithmetic operations

211. Now we get to some interesting bits.

We have `_Add` for the addition of two non-negative integers. The basic strategy is to go digit-by-digit, use the PASCAL-provided integer arithmetic, manually “carrying” 1 if necessary.

The basic strategy is to initialize `a1` to be the larger of the two numbers, and `b1` to the smaller of the two numbers. Then generically we will have

$$\begin{array}{r} a_n \dots a_{m+1} \ a_m \ a_{m-1} \dots a_1 \\ + \qquad \qquad \qquad b_m \ b_{m-1} \dots b_1 \\ \hline \end{array} \quad (211.1)$$

We will separate this out into two sums. First we compute

$$\begin{array}{r} a_m \ a_{m-1} \dots a_1 \\ + \ b_m \ b_{m-1} \dots b_1 \\ \hline c_{m+1} \ r_m \ r_{m-1} \dots r_1 \end{array} \quad (211.2)$$

Then we will compute

$$\begin{array}{r} a_n \dots a_{m+1} \\ + \qquad \qquad \qquad c_{m+1} \\ \hline r_{n+1} \ r_n \dots r_{m+1} \end{array} \quad (211.3)$$

The result is assembled from the digits $r_{n+1}r_n \dots r_1$.

⟨Arithmetic for arbitrary-precision integers 211⟩ ≡

```
function _Add(a, b : String): string;
  var c, x, y, z, v: integer; i: integer; a1, b1, s, r: string;
  begin ⟨Copy a and b into a1, b1 ensuring a1 is a longer string 212⟩;
  r ← “”; c ← 0;
  begin ⟨Add a1 and b1 as in step 1, Eq (211.2) 213⟩;
  ⟨Carry the cm+1 as in step 2, Eq (211.3) 214⟩;
  end; _Add ← trimlz(r);
end;
```

See also sections 215, 219, 221, 224, 226, 233, 235, 237, 239, 244, 249, 251, 253, and 255.

This code is used in section 198.

```
212. ⟨Copy a and b into a1, b1 ensuring a1 is a longer string 212⟩ ≡
  a1 ← a; b1 ← b; debug_num(WriteLn(infofile, “_Add(“, a1, “”, b1, “)”)); checkzero(a1, b1);
  if length(a1) < length(b1) then
    begin s ← b1; b1 ← a1; a1 ← s;
    end
```

This code is used in section 211.

```
213. ⟨Add a1 and b1 as in step 1, Eq (211.2) 213⟩ ≡
  for i ← 0 to length(b1) − 1 do {step 1, Eq (211.2)}
    begin val(a1[length(a1) − i], x, z); val(b1[length(b1) − i], y, z);
    if x + y + c > 9 then
      begin v ← (x + y + c) − 10; c ← 1;
      end
    else begin v ← x + y + c; c ← 0;
    end;
    Str(v, s); r ← s + r;
  end
```

This code is used in section 211.

214. $\langle \text{Carry the } c_{m+1} \text{ as in step 2, Eq (211.3) } \mathbf{214} \rangle \equiv$
for $i \leftarrow \text{length}(b1)$ **to** $\text{length}(a1) - 1$ **do** { step 2, Eq (211.3) }
 begin $\text{val}(a1[\text{length}(a1) - i], x, z);$
 if $x + c > 9$ **then**
 begin $v \leftarrow (x + c) - 10; c \leftarrow 1;$
 end
 else begin $v \leftarrow x + c; c \leftarrow 0;$
 end;
 $\text{Str}(v, s); r \leftarrow s + r;$
 end;
if $c = 1$ **then** $r \leftarrow \text{'1'} + r$

This code is used in section [211](#).

215. Subtraction is a bit trickier, because of the “borrowing” operation.

Also note that $\text{Sub}(a, b)$ will start by computing $a_1 \leftarrow \max(a, b)$ and $b_1 \leftarrow \min(a, b)$, then return $a_1 - b_1$. This means the result is always non-negative.

$\langle \text{Arithmetic for arbitrary-precision integers } \mathbf{211} \rangle + \equiv$
function $\text{Sub}(a, b : \text{string}) : \text{string};$
 var $x, y, z, v : \text{integer}; i : \text{integer}; a1, b1, s, r : \text{string};$
 $\langle \text{“Borrow 1” procedure for Sub } \mathbf{216} \rangle$
 begin $a1 \leftarrow a; b1 \leftarrow b;$
 $\text{debug_num}(\text{WriteLn}(\text{infofile}, \text{'_Sub('}, a1, \text{'}, \text{'}, b1, \text{'})'}));$
 $\text{checkzero}(a1, b1); \langle \text{Swap } a1 \text{ and } b1 \text{ if } b1 \leq a1 \mathbf{217} \rangle;$
 $r \leftarrow \text{''};$
 begin
 for $i \leftarrow 0$ **to** $\text{length}(b1) - 1$ **do** $\langle \text{Subtract the } i^{\text{th}} \text{ digit of } b1 \text{ from } a1 \mathbf{218} \rangle;$
 for $i \leftarrow \text{length}(a1) - \text{length}(b1)$ **downto** 1 **do** { nothing left to subtract }
 begin $r \leftarrow a1[i] + r;$ **end;** { so copy remaining digits of minuend }
 end;
 $\text{Sub} \leftarrow \text{trimlz}(r);$
end ;

216. This is a private “helper function” for subtraction.

$\langle \text{“Borrow 1” procedure for Sub } \mathbf{216} \rangle \equiv$
procedure $\text{Borrow}(k : \text{integer});$
 var $xx, zz : \text{integer}; sx : \text{string};$
 begin $\text{val}(a1[k - 1], xx, zz);$
 if $xx \geq 1$ **then**
 begin $xx \leftarrow xx - 1; \text{Str}(xx, sx); a1[k - 1] \leftarrow sx[1];$
 end
 else begin $a1[k - 1] \leftarrow \text{'9'}; \text{borrow}(k - 1);$
 end;
 end;

This code is used in section [215](#).

217. $\langle \text{Swap } a1 \text{ and } b1 \text{ if } b1 \leq a1 \mathbf{217} \rangle \equiv$
 if $\neg \text{leq}(b1, a1)$ **then**
 begin $s \leftarrow b1; b1 \leftarrow a1; a1 \leftarrow s;$
 end

This code is used in section [215](#).

218. We compute $v = x - y$ where $x \leftarrow (a1)_i$ (possibly borrowing from the next digit of $a1$) and $y \leftarrow (b1)_i$. We store this as the next digit in the result r .

\langle Subtract the i^{th} digit of $b1$ from $a1$ 218 $\rangle \equiv$
begin $val(a1[length(a1) - i], x, z); val(b1[length(b1) - i], y, z);$
if $x < y$ **then**
 begin $borrow(length(a1) - i); x \leftarrow x + 10;$ **end**;
 $v \leftarrow x - y; Str(v, s); r \leftarrow s + r;$
end

This code is used in section 215.

219. Multiplication. Multiplication of a by b works digit-by-digit, in the sense that for each digit b_j of b , we need to multiply a by b_j . The function `_Mul1` does this.

\langle Arithmetic for arbitrary-precision integers 211 $\rangle + \equiv$
function `_Mul1`($a : string; y : integer$): $string$;
 var $c, x, z, v : integer; i : integer; s, r : string$;
 begin $debug_num(WriteLn(infofile, _Mul1(_, a, _, _, y, _)))$;
 $r \leftarrow _0$; $c \leftarrow 0$;
 for $i \leftarrow 0$ **to** $length(a) - 1$ **do** \langle Multiply i^{th} digit of a by y 220 \rangle ;
 if $c \neq 0$ **then**
 begin $Str(c, s); r \leftarrow s + r$;
 end;
 $_mul1 \leftarrow trimlz(r)$;
end;

220. \langle Multiply i^{th} digit of a by y 220 $\rangle \equiv$
begin $val(a[length(a) - i], x, z)$;
if $x * y + c > 9$ **then**
 begin $v \leftarrow (x * y + c) \bmod 10; c \leftarrow (x * y + c) \div 10$;
 end
else begin $v \leftarrow x * y + c; c \leftarrow 0$;
 end;
 $Str(v, s); r \leftarrow s + r$;
end

This code is used in section 219.

221. Then multiplication proper amounts to decomposing b into its decimal expansion $\sum_k b_k 10^k$ and computing $(a \times b_k) 10^k$.

\langle Arithmetic for arbitrary-precision integers 211 $\rangle + \equiv$
function `_Mul`($a, b : string$): $string$;
 var $y, z : integer; i, j : integer; a1, b1, s, r : string$;
 begin \langle Copy a into $a1$ and b into $b1$, ensuring $b1$ is a shorter string 222 \rangle ;
 $r \leftarrow _0$;
 for $i \leftarrow 0$ **to** $length(b1) - 1$ **do** \langle Multiply i^{th} digit of $b1$ to $a1$ and add it to r 223 \rangle ;
 $_Mul \leftarrow trimlz(r)$;
end;

222. $\langle \text{Copy } a \text{ into } a1 \text{ and } b \text{ into } b1, \text{ ensuring } b1 \text{ is a shorter string } 222 \rangle \equiv$
 $a1 \leftarrow a; b1 \leftarrow b;$
 $debug_num(WriteLn(infofile, \text{'_Mul' }, a1, \text{' }, b1, \text{' }));$
 $checkzero(a1, b1);$
if $length(a1) < length(b1)$ **then**
 begin $s \leftarrow b1; b1 \leftarrow a1; a1 \leftarrow s;$ **end**

This code is used in section 221.

223. $\langle \text{Multiply } i^{\text{th}} \text{ digit of } b1 \text{ to } a1 \text{ and add it to } r \text{ } 223 \rangle \equiv$
begin $val(b1[length(b1) - i], y, z); s \leftarrow _mul1(a1, y);$
for $j \leftarrow 0$ **to** $i - 1$ **do** $s \leftarrow s + \text{'0'}$;
 $r \leftarrow _Add(r, s);$
end

This code is used in section 221.

224. Division. The basic design is similar to multiplication. We will try to divide a by b (which is zero whenever $b > a$). When $b \leq a$, then a/b is the largest digit $i \in \{1, 2, \dots, 9\}$ such that $bi \leq a$.

There appears to be an implicit assumption that $a < 10b$, and both $a \geq 0$ and $b \geq 0$ are non-negative integers.

[[There is no leading zero to r , so the $trimlz(r)$ statement is completely superfluous.]]

$\langle \text{Arithmetic for arbitrary-precision integers } 211 \rangle + \equiv$

function $_Div1(a, b : string) : string;$
var $i : integer; r : string;$
begin $debug_num(WriteLn(infofile, \text{'_Div1' }, a, \text{' }, b, \text{' }));$
 $checkzero(a, b);$
if $\neg_leq(b, a)$ **then** $_div1 \leftarrow \text{'0'}$ { $a/b = 0$ when $b > a$ }
else for $i \leftarrow 9$ **downto** 1 **do**
 begin $Str(i, r);$
 if $_leq(_mul(b, r), a)$ **then**
 begin $_div1 \leftarrow trimlz(r); exit;$
 end;
 end;
end;

225. Calculate q such that $a = bq + r$ for some $0 \leq r < b$, assuming $a \geq 0$ and $b \geq 0$.

$\langle \text{Basic arithmetic operations declarations } 204 \rangle + \equiv$

function $_Div(a, b : string) : string;$

226. $\langle \text{Arithmetic for arbitrary-precision integers } 211 \rangle + \equiv$

function $_Div(a, b : string) : string;$
var $z, c, i : integer; s, r, rs : string; b_GPC : Boolean;$
 $\langle \text{Get the next digit for dividing arbitrary-precision integers } 229 \rangle$
begin $debug_num(WriteLn(infofile, \text{'_Div' }, a, \text{' }, b, \text{' }));$
 $checkzero(a, b);$
if $a = b$ **then** $_div \leftarrow \text{'1'}$
else if $\neg_leq(b, a)$ **then** $_div \leftarrow \text{'0'}$
else $\langle \text{Long division of } a \text{ by } b \text{ } 227 \rangle;$
end;

227. We take the leading digits of a and treat them as a new integer $s = a_1 \cdots a_z$. We only take as many digits necessary to make $b \leq s$ but with $a_1 \cdots a_{z-1} < b$. Then we compute rs such that $s = b \times rs + r$ for some $0 \leq r < b$. We update $s \leftarrow s - rs \times b$ and move to the next digit of a (updating s) using the *gets* function. This reflects “long division” as taught in gradeschool.

```

⟨ Long division of  $a$  by  $b$  227 ⟩ ≡
  begin  $s \leftarrow \text{``}$ ;  $r \leftarrow \text{``}$ ;  $z \leftarrow 1$ ;
  for  $i \leftarrow 1$  to  $\text{length}(b)$  do  $s \leftarrow s + a[i]$ ; { copy leading digits of  $a$  into  $s$  }
  ⟨ Ensure  $b \leq s$  by adding another digit of  $a$ , initialize  $z$  228 ⟩; {  $z \leftarrow \text{length}(s)$  }
  repeat  $rs \leftarrow \text{\_div1}(s, b)$ ;  $r \leftarrow r + rs$ ; gets;  $b\_GPC \leftarrow \text{\_leq}(b, s)$ ;
  until  $\neg b\_GPC$ ;
   $\text{\_div} \leftarrow \text{trimlz}(r)$ ;
end

```

This code is used in section 226.

228. ⟨ Ensure $b \leq s$ by adding another digit of a , initialize z 228 ⟩ ≡

```

  if  $\text{\_leq}(b, s)$  then  $z \leftarrow \text{length}(b)$ 
  else begin  $s \leftarrow s + a[\text{length}(b) + 1]$ ;  $z \leftarrow \text{length}(b) + 1$ ; end

```

This code is used in section 227.

229. We just need to “get the next digit” of a , if available, and append it to s .

```

  define remaining_digits_are_zero ≡ ( $\text{trimlz}(\text{copy}(a, z + c, \text{length}(a))) = \text{``0``}$ )
⟨ Get the next digit for dividing arbitrary-precision integers 229 ⟩ ≡
  procedure gets;
  var  $j$ : integer;
  begin  $c \leftarrow 1$ ;  $s \leftarrow \text{\_Sub}(s, \text{\_mul}(rs, b))$ ; { i.e.,  $s \leftarrow s \bmod b$  }
  if  $(s = \text{``0``}) \wedge \text{remaining\_digits\_are\_zero}$  then
    ⟨ Copy remainder of  $a$  into  $s$ , and terminate the function 230 ⟩;
  if  $z + 1 \leq \text{length}(a)$  then ⟨ Append next digit of  $a$  onto  $s$ , incrementing  $c$  231 ⟩;
  while  $(\neg \text{\_leq}(b, s)) \wedge (z + c \leq \text{length}(a))$  do ⟨ Append next digit of  $a$  onto  $s$ , incrementing  $c$  231 ⟩;
   $z \leftarrow z + c - 1$ ;
  end; { gets }

```

This code is used in section 226.

230. ⟨ Copy remainder of a into s , and terminate the function 230 ⟩ ≡

```

  begin debug_num( $\text{WriteLn}(\text{infofile}, \text{``Rewriting\_zeros:``}, \text{copy}(a, z + c, \text{length}(a))))$ );
   $r \leftarrow r + \text{copy}(a, z + c, \text{length}(a))$ ; exit;
end

```

This code is used in section 229.

231. ⟨ Append next digit of a onto s , incrementing c 231 ⟩ ≡

```

  begin  $s \leftarrow s + a[z + c]$ ; inc( $c$ );
  if  $(\neg \text{\_leq}(b, s))$  then  $r \leftarrow r + \text{``0``}$ ; { shortcut: division will add a zero digit anyways }
end

```

This code is used in sections 229 and 229.

232. Modulo. We can compute $a \bmod b$ by observing if $a < b$ then we should obtain a . Otherwise, we should compute $q \leftarrow a \text{ div } b$, then $a - qb$ is $a \bmod b$.

```

⟨ Basic arithmetic operations declarations 204 ⟩ +=
function \_Mod( $a, b$ : string): string;

```

233. \langle Arithmetic for arbitrary-precision integers 211 $\rangle + \equiv$

```
function _Mod(a, b : string): string;
  var r: string;
  begin debug_num( WriteLn( infofile, ^_Mod(^, a, ^, ^, b, ^) ));
    checkzero(a, b);
    if le(a, b) then r ← a
    else r ← _Sub(a, _Mul(b, _Div(a, b)));
    _Mod ← trimlz(r);
    debug_num( WriteLn( infofile, ^End_ _Mod: ^, r ));
  end;
```

234. Greatest common divisor. We can compute $\gcd(a, b)$ first by setting $a_1 \leftarrow |a|$ and $b_1 \leftarrow |b|$ (since $\gcd(a, b) = \gcd(|a|, |b|)$). Then we handle the special cases:

- (1) $a_1 = 1$ or $b_1 = 1$, then $\gcd(a_1, b_1) = 1$
- (2) $a_1 = 0$ and $b_1 \neq 0$, then $\gcd(a_1, b_1) = b_1$
- (3) $a_1 \neq 0$ and $b_1 = 0$, then $\gcd(a_1, b_1) = a_1$
- (4) $a_1 = b_1$, then $\gcd(a_1, b_1) = a_1$

Otherwise, we end up in the default case, which is handled by the **while** loop.

```
define assign_gcd_and_jump(#) ≡
  begin r ← #; goto ex; end
 $\langle$  Basic arithmetic operations declarations 204  $\rangle + \equiv$ 
function GCD(a, b : string): string; { *Note: always returns a positive value }
```

235. \langle Arithmetic for arbitrary-precision integers 211 $\rangle + \equiv$

```
function GCD(a, b : string): string;
  label ex;
  var a1, b1, p, r: string;
  begin a1 ← a; b1 ← b;
    debug_num( WriteLn( infofile, ^GCD(^, a1, ^, ^, b1, ^) ));
    checkzero(a1, b1); a1 ← abs(a1); b1 ← abs(b1);
    if (a1 = ^1^ ) ∨ (b1 = ^1^ ) then assign_gcd_and_jump(^1^ );
    if (a1 = ^0^ ) ∧ (b1 ≠ ^0^ ) then assign_gcd_and_jump(b1);
    if (b1 = ^0^ ) ∧ (a1 ≠ ^0^ ) then assign_gcd_and_jump(a1);
    if a1 = b1 then assign_gcd_and_jump(a1);
    while gt(b1, ^0^ ) do { 0 < b1 }
      begin p ← b1; b1 ← _Mod(a1, b1); a1 ← p end;
    r ← a1;
  ex: GCD ← r;
    debug_num( WriteLn( infofile, ^End_ GCD: ^, r ));
  end;
```

236. Least common multiple. We recall $\text{lcm}(a, b) = |ab| / \gcd(|a|, |b|)$.

\langle Basic arithmetic operations declarations 204 $\rangle + \equiv$
function LCM(a, b : string): string; { *Note: always returns a positive value }

237. $\langle \text{Arithmetic for arbitrary-precision integers } 211 \rangle + \equiv$

```
function LCM( $a, b : \text{string}$ ):  $\text{string}$ ;
  var  $a1, b1, r : \text{string}$ ;
  begin  $a1 \leftarrow a$ ;  $b1 \leftarrow b$ ;
   $\text{debug\_num}(\text{WriteLn}(\text{infofile}, \text{'LCM('}, a1, \text{'}, b1, \text{'})'}$ ));
   $\text{checkzero}(a1, b1)$ ;  $a1 \leftarrow \text{abs}(a1)$ ;  $b1 \leftarrow \text{abs}(b1)$ ;  $r \leftarrow \text{DivA}(\text{Mul}(a1, b1), \text{GCD}(a1, b1))$ ;  $\text{LCM} \leftarrow r$ ;
   $\text{debug\_num}(\text{WriteLn}(\text{infofile}, \text{'End\_LCM:'}, r))$ ;
  end;
```

238. Addition. This is a bit obfuscated with the reliance of **goto** *ex*, but the basic idea is (recalling that $\text{Sub}(a, b)$ calculates $\max(a, b) - \min(a, b)$ for $a \geq 0$ and $b \geq 0$):

- (1) If $a < 0$ and $b < 0$, then $a + b = -(|a| + |b|)$
- (2) Else if $a \geq 0$ and $b \geq 0$, then $a + b$ is computed using Add
- (3) Else if $a < 0$ and $b \geq 0$, then we have two cases
 - (i) If $|a| \geq b$, compute $a + b = -(|a| - b)$
 - (ii) Otherwise, $a + b = b - |a|$
- (4) Else if $a \geq 0$ and $b < 0$, then $a + b = a - |b|$
- (5) Otherwise, when $a \geq 0$ and $b \geq 0$, $a + b$ is computed using Add .

$\langle \text{Basic arithmetic operations declarations } 204 \rangle + \equiv$

```
function Add( $a, b : \text{string}$ ):  $\text{string}$ ;
```

239. $\langle \text{Arithmetic for arbitrary-precision integers } 211 \rangle + \equiv$

```
function Add( $a, b : \text{string}$ ):  $\text{string}$ ;
  label  $ex$ ;
  var  $r : \text{string}$ ;
  begin  $\text{debug\_num}(\text{WriteLn}(\text{infofile}, \text{'Add('}, a, \text{'}, b, \text{'})'}$ ));
   $\text{checkzero}(a, b)$ ;

  if  $r = \text{'-0'}$  then  $r \leftarrow \text{'0'}$ ;
  goto  $ex$ ;
  end
else begin  $r \leftarrow \text{Sub}(\text{abs}(a), b)$ ; goto  $ex$ ; end
```

This code is used in section 239.

242. $\langle \text{Calculate } a + (-b) = a - b \text{ and goto } ex \text{ 242} \rangle \equiv$
if $gt(abs(b), a)$ **then**
 begin $r \leftarrow '-' + _Sub(abs(b), a);$
 if $r = '-0'$ **then** $r \leftarrow '0';$
 goto $ex;$
 end
else begin $r \leftarrow _Sub(abs(b), a);$ **goto** $ex;$ **end**

This code is used in section 239.

243. Subtraction. Now, given two arbitrary precision integers, we can compute their difference. Again, **goto** ex obfuscates the flow here, but the basic logic is:

- (1) If $a < 0$ and $b \geq 0$, then $a - b = -(|a| + b)$
- (2) Else if $a \geq 0$ and $b < 0$, then $a - b = a + |b|$
- (3) Else if $a < 0$ and $b < 0$, then we have two cases
 - (i) If $|a| > |b|$, then $a - b = -(|a| - |b|)$
 - (ii) Otherwise $|a| \leq |b|$, so $a - b = |a| - |b|$
- (4) Else if $a \geq 0$ and $b \geq 0$, then we have two cases
 - (i) If $b > a$, then $a - b = -(b - a)$
 - (ii) Otherwise compute $a - b$ using $_Sub(a, b)$

Testing if $x < 0$ is done by checking $sgn(x) = -1$, and $x \geq 0$ tests if $sgn(x) \neq -1$.

$\langle \text{Basic arithmetic operations declarations 204} \rangle + \equiv$

function $Sub(a, b : string) : string;$

244. $\langle \text{Arithmetic for arbitrary-precision integers 211} \rangle + \equiv$

function $Sub(a, b : string) : string;$
 label $ex;$
 var $r : string;$
 begin $debug_num(WriteLn(infofile, 'Sub(' , a, ', ', b, ')');$
 $checkzero(a, b);$

246. $\langle \text{Calculate } (-a) - (-b) \text{ and } \text{goto } ex \text{ 246} \rangle \equiv$
if $gt(abs(a), abs(b))$ **then**
 begin $r \leftarrow '-' + _Sub(abs(a), abs(b));$
 if $r = '-0'$ **then** $r \leftarrow '0';$
 goto $ex;$
 end
else begin $r \leftarrow _Sub(abs(a), abs(b));$ **goto** $ex;$ **end**

This code is used in section 244.

247. $\langle \text{Calculate difference of two positive integers 247} \rangle \equiv$
if $gt(b, a)$ **then**
 begin $r \leftarrow '-' + _Sub(b, a);$
 if $r = '-0'$ **then** $r \leftarrow '0';$
 goto $ex;$
 end
else begin $r \leftarrow _Sub(a, b);$ **goto** $ex;$ **end**

This code is used in section 244.

248. Multiplication of arbitrary-precision integers. We calculate the product of a with b by handling the case where $\text{sgn}(a) \neq \text{sgn}(b)$ as $ab = -|a| \cdot |b|$. Otherwise we can just rely on the $_Mul(a, b)$ to do our work.

$\langle \text{Basic arithmetic operations declarations 204} \rangle + \equiv$
function $Mul(a, b : string) : string;$

249. $\langle \text{Arithmetic for arbitrary-precision integers 211} \rangle + \equiv$
function $Mul(a, b : string) : string;$
 label $ex;$
 var $r : string;$
 begin $debug_num(WriteLn(infofile, 'Mul(' , a , ', ' , b , ')');$
 $checkzero(a, b);$
 if $((a[1] = '-' \wedge (b[1] \neq '-')) \vee ((a[1] \neq '-') \wedge (b[1] = '-')))$ **then**
 begin $r \leftarrow '-' + _Mul(abs(a), abs(b));$
 if $r = '-0'$ **then** $r \leftarrow '0';$
 end
 else $r \leftarrow _Mul(abs(a), abs(b));$
 $ex : Mul \leftarrow r;$
 $debug_num(WriteLn(infofile, 'End_Mul: ' , r));$
 end;

250. DivA. This is the division for arbitrary-precision integers. Like multiplication, we handle the case $\text{sgn}(a) \neq \text{sgn}(b)$ by computing $a/b = -|a|/|b|$.

$\langle \text{Basic arithmetic operations declarations 204} \rangle + \equiv$
function $DivA(a, b : string) : string;$
 { *Note: divides absolute values and preserves the sign of the division }

251. \langle Arithmetic for arbitrary-precision integers 211 $\rangle + \equiv$

```
function DivA(a, b : string): string;
  label ex;
  var r: string;
  begin debug_num( WriteLn( infofile, 'DivA( ', a, ', ', b, ' )' ));
  checkzero(a, b);
  if ((a[1] = '-' )  $\wedge$  (b[1]  $\neq$  '-' ))  $\vee$  ((a[1]  $\neq$  '-' )  $\wedge$  (b[1] = '-' )) then
    begin r  $\leftarrow$  '-' + _Div(abs(a), abs(b));
    if r = '-0' then r  $\leftarrow$  '0';
    end
  else r  $\leftarrow$  _Div(abs(a), abs(b));
ex: DivA  $\leftarrow$  r;
  debug_num( WriteLn( infofile, 'End_DivA: ', r ));
end;
```

252. Testing for primality. We can test if a given arbitrary-precision integer is prime or not. Specifically, we restrict attention to *positive* integers.

The **while** loop calculates $Mul(i, i)$ because Fermat observed we only need to check numbers *up to* $\lceil \sqrt{x} \rceil$ as prime factors of x . But this calculation is a bit costly. This could be approximated by taking the length of the underlying String $n = |s|$ and looking at the leading $\lceil n/2 \rceil$ digits s_{lead} . It's not hard to see that the number x_{lead} described by s_{lead} satisfies $x_{lead}^2 \geq x$.

\langle Basic arithmetic operations declarations 204 $\rangle + \equiv$

```
function IsPrime(a : string): Boolean;
```

253. \langle Arithmetic for arbitrary-precision integers 211 $\rangle + \equiv$

```
function IsPrime(a : string): Boolean;
  var i: string; r: Boolean;
  begin if leq('2', a) then
    begin r  $\leftarrow$  true; i  $\leftarrow$  '2';
    while leq(Mul(i, i), a) do
      begin if GCD(a, i) = i then
        begin r  $\leftarrow$  false; break; end;
      i  $\leftarrow$  Add(i, '1');
    end;
  else r  $\leftarrow$  false;
  IsPrime  $\leftarrow$  r;
end;
```

254. Divides relation. We can check if “ x divides y ” by testing if $\gcd(x, y) = |x|$.

\langle Basic arithmetic operations declarations 204 $\rangle + \equiv$

```
function Divides(a, b : String): boolean;
```

255. \langle Arithmetic for arbitrary-precision integers 211 $\rangle + \equiv$

```
function Divides(a, b : string): Boolean;
  var r: Boolean;
  begin r  $\leftarrow$  GCD(a, b) = abs(a); Divides  $\leftarrow$  r;
end;
```

Section 9.2. ARBITRARY-PRECISION RATIONAL ARITHMETIC

256. Rational numbers are a pair of arbitrary precision integers (represented as a String). The convention is that the denominator is a *strictly positive* integer.

⟨Types for arbitrary-precision arithmetic 256⟩ ≡
`Rational = record Num, Den: string
 end;`

See also section 276.

This code is used in section 198.

257. “Zero” and “one” are frequently used rational numbers, so we should define them as constants.

⟨Zero and units for arbitrary-precision 257⟩ ≡
`RZero: Rational = (Num : ^0^; Den : ^1^);
 ROne: Rational = (Num : ^1^; Den : ^1^);`

See also section 277.

This code is used in section 198.

258. Rational arithmetic. Now we begin the rational arithmetic “in earnest”. The first thing to do is provide a way to compute the reduced form for a fraction, i.e.,

$$\frac{n}{d} = \frac{n/\gcd(n,d)}{d/\gcd(n,d)}$$

⟨Rational arithmetic declarations 258⟩ ≡
procedure *RationalReduce*(**var** *r* : *Rational*);

See also sections 260, 262, 264, 266, 268, 270, 272, and 274.

This code is used in section 198.

259. ⟨Arbitrary-precision rational arithmetic 259⟩ ≡
procedure *RationalReduce*(**var** *r* : *Rational*);
`var lGcd: String;
 begin lGcd ← gcd(r.Num, r.Den); r.Num ← diva(r.Num, lGcd); r.Den ← diva(r.Den, lGcd);
 end;`

See also sections 261, 263, 265, 267, 269, 271, 273, and 275.

This code is used in section 198.

260. Rational addition. We recall

$$\frac{a}{b} + \frac{c}{d} = \frac{ad + bc}{bd}$$

We should return the reduced form of the result.

⟨Rational arithmetic declarations 258⟩ +=
function *RationalAdd*(**const** *r1*, *r2* : *Rational*): *Rational*;

261. ⟨Arbitrary-precision rational arithmetic 259⟩ +=
function *RationalAdd*(**const** *r1*, *r2* : *Rational*): *Rational*;
`var lRes: Rational;
 begin lRes.Num ← Add(Mul(r1.Num, r2.Den), Mul(r1.Den, r2.Num));
 lRes.Den ← Mul(r1.Den, r2.Den); RationalReduce(lRes); RationalAdd ← lRes;
 end;`

262. Rational subtraction. Similar to addition, but the numerator is $ad - bc$.

\langle Rational arithmetic declarations 258 $\rangle + \equiv$
function *RationalSub*(**const** $r1, r2$: *Rational*): *Rational*;

263. \langle Arbitrary-precision rational arithmetic 259 $\rangle + \equiv$
function *RationalSub*(**const** $r1, r2$: *Rational*): *Rational*;
var $lRes$: *Rational*;
begin $lRes.Num \leftarrow Sub(Mul(r1.Num, r2.Den), Mul(r1.Den, r2.Num));$
 $lRes.Den \leftarrow Mul(r1.Den, r2.Den);$ *RationalReduce*($lRes$); *RationalSub* $\leftarrow lRes$;
end;

264. Negating a rational number amounts to multiplying the numerator by -1 .

\langle Rational arithmetic declarations 258 $\rangle + \equiv$
function *RationalNeg*(**const** $r1$: *Rational*): *Rational*;

265. \langle Arbitrary-precision rational arithmetic 259 $\rangle + \equiv$
function *RationalNeg*(**const** $r1$: *Rational*): *Rational*;
var $lRes$: *Rational*;
begin $lRes.Num \leftarrow Mul(\text{'-1'}, r1.Num);$ $lRes.Den \leftarrow r1.Den;$ *RationalNeg* $\leftarrow lRes$;
end;

266. Multiplying rational numbers. This uses the school-book formula

$$\frac{a}{b} \times \frac{c}{d} = \frac{ac}{bd}$$

\langle Rational arithmetic declarations 258 $\rangle + \equiv$
function *RationalMult*(**const** $r1, r2$: *Rational*): *Rational*;

267. \langle Arbitrary-precision rational arithmetic 259 $\rangle + \equiv$
function *RationalMult*(**const** $r1, r2$: *Rational*): *Rational*;
var $lRes$: *Rational*;
begin $lRes.Num \leftarrow Mul(r1.Num, r2.Num);$ $lRes.Den \leftarrow Mul(r1.Den, r2.Den);$ *RationalReduce*($lRes$);
RationalMult $\leftarrow lRes$;
end;

268. Inverting a rational number. This is easy, provided the numerator is nonzero. The convention is to make the numerator carry the sign of the number (so n/d has $n \in \mathbf{Z}$ while $d \in \mathbf{N}$).

When the rational number *is* zero, we simply take $0^{-1} = 0$ (as is conventional among proof assistants).

\langle Rational arithmetic declarations 258 $\rangle + \equiv$
function *RationalInv*(**const** r : *Rational*): *Rational*;

269. \langle Arbitrary-precision rational arithmetic 259 $\rangle + \equiv$

```
function RationalInv(const r: Rational): Rational;
  var lRes: Rational;
  begin if r.Num  $\neq$  '0' then
    begin if le(r.Num, '0') then lRes.Num  $\leftarrow$  Mul('−1', r.Den)
    else lRes.Num  $\leftarrow$  r.Den;
    lRes.Den  $\leftarrow$  Abs(r.Num);
    end
  else lRes  $\leftarrow$  RZero;
  RationalInv  $\leftarrow$  lRes;
  end;
```

270. Dividing rational numbers. We see that $r_1/r_2 = r_1 \times (r_2^{-1})$. That's the trick.

\langle Rational arithmetic declarations 258 $\rangle + \equiv$

```
function RationalDiv(const r1, r2: Rational): Rational;
```

271. \langle Arbitrary-precision rational arithmetic 259 $\rangle + \equiv$

```
function RationalDiv(const r1, r2: Rational): Rational;
  begin RationalDiv  $\leftarrow$  RationalMult(r1, RationalInv(r2));
  end;
```

272. Equality of rational numbers. Two rational numbers n_1/d_1 and n_2/d_2 are equal if $n_1 = n_2$ and $d_1 = d_2$. This assumes that both rational numbers are in reduced form.

\langle Rational arithmetic declarations 258 $\rangle + \equiv$

```
function RationalEq(const r1, r2: Rational): boolean;
```

273. \langle Arbitrary-precision rational arithmetic 259 $\rangle + \equiv$

```
function RationalEq(const r1, r2: Rational): boolean;
  begin RationalEq  $\leftarrow$  (r1.Num = r2.Num)  $\wedge$  (r1.Den = r2.Den);
  end;
```

274. Testing inequality of rational numbers. We have $n_1/d_1 \leq n_2/d_2$ if $n_1 d_2 \leq n_2 d_1$.

Similarly, we have $n_1/d_1 > n_2/d_2$ is just the negation of $n_1/d_1 \leq n_2/d_2$.

\langle Rational arithmetic declarations 258 $\rangle + \equiv$

```
function RationalLE(const r1, r2: Rational): boolean;
```

```
function RationalGT(const r1, r2: Rational): boolean;
```

275. \langle Arbitrary-precision rational arithmetic 259 $\rangle + \equiv$

```
function RationalLE(const r1, r2: Rational): boolean;
  begin RationalLE  $\leftarrow$  leq(Mul(r1.Num, r2.Den), Mul(r1.Den, r2.Num));
  end;
function RationalGT(const r1, r2: Rational): boolean;
  begin RationalGT  $\leftarrow$   $\neg$  RationalLE(r1, r2);
  end;
```

Section 9.3. RATIONAL COMPLEX NUMBERS

276. We now begin with $\mathbf{Q} + i\mathbf{Q} \subseteq \mathbf{C}$, the subset of complex-numbers where the real and imaginary parts are rational numbers.

That is to say, rational complex numbers are represented by a pair of rational numbers in Cartesian form $z = p + iq$.

\langle Types for arbitrary-precision arithmetic 256 $\rangle + \equiv$
 $RComplex = \mathbf{record} \text{ } Re, Im: Rational$
 $\mathbf{end};$

277. \langle Zero and units for arbitrary-precision 257 $\rangle + \equiv$
 $CZero: RComplex = (Re : (Num : ^0^; Den : ^1^); Im : (Num : ^0^; Den : ^1^));$
 $COne: RComplex = (Re : (Num : ^1^; Den : ^1^); Im : (Num : ^0^; Den : ^1^));$
 $CMinusOne: RComplex = (Re : (Num : ^-1^; Den : ^1^); Im : (Num : ^0^; Den : ^1^));$
 $CImUnit: RComplex = (Re : (Num : ^0^; Den : ^1^); Im : (Num : ^1^; Den : ^1^));$

278. We want to know when these numbers describe integers (i.e., the imaginary part is zero and the denominator of the real part is 1) and natural numbers (i.e., when furthermore the numerator of the real part is non-negative).

\langle Predicate declarations for arbitrary-precision arithmetic 278 $\rangle \equiv$
 $\mathbf{function} \text{ } IsIntegerNumber(\mathbf{const} \text{ } z: RComplex): Boolean;$
 $\mathbf{function} \text{ } IsNaturalNumber(\mathbf{const} \text{ } z: RComplex): Boolean;$
 $\mathbf{function} \text{ } IsPrimeNumber(\mathbf{const} \text{ } z: RComplex): Boolean;$

See also sections 280 and 282.

This code is used in section 198.

279. \langle Complex-rational arbitrary-precision arithmetic 279 $\rangle \equiv$
 $\mathbf{function} \text{ } IsIntegerNumber(\mathbf{const} \text{ } z: RComplex): Boolean;$
 $\mathbf{begin} \text{ } IsIntegerNumber \leftarrow (z.Im.Num = ^0^) \wedge (z.Re.Den = ^1^); \mathbf{end};$
 $\mathbf{function} \text{ } IsNaturalNumber(\mathbf{const} \text{ } z: RComplex): Boolean;$
 $\mathbf{begin} \text{ } IsNaturalNumber \leftarrow (z.Im.Num = ^0^) \wedge (z.Re.Den = ^1^) \wedge (geq(z.Re.Num, ^0^)); \mathbf{end};$
 $\mathbf{function} \text{ } IsPrimeNumber(\mathbf{const} \text{ } z: RComplex): boolean;$
 $\mathbf{begin} \text{ } \mathbf{if} \text{ } IsNaturalNumber(z) \wedge IsPrime(z.Re.Num) \mathbf{then} \text{ } IsPrimeNumber \leftarrow true$
 $\mathbf{else} \text{ } IsPrimeNumber \leftarrow false;$
 $\mathbf{end};$

See also sections 281, 283, 285, 287, 289, 291, 293, 296, 299, 301, 303, and 305.

This code is used in section 198.

280. Equality of complex numbers. This amounts to checking if the real and imaginary parts are equal to each other as rational numbers.

\langle Predicate declarations for arbitrary-precision arithmetic 278 $\rangle + \equiv$
 $\mathbf{function} \text{ } AreEqComplex(\mathbf{const} \text{ } z1, z2: RComplex): Boolean;$
 $\mathbf{function} \text{ } IsEqWithInt(\mathbf{const} \text{ } z: RComplex;$
 $\text{ } n: longint): Boolean;$

281. \langle Complex-rational arbitrary-precision arithmetic 279 $\rangle + \equiv$
function *AreEqComplex*(**const** $z1, z2$: *RComplex*): *Boolean*;
 begin *AreEqComplex* \leftarrow *RationalEq*($z1.Re, z2.Re$) \wedge *RationalEq*($z1.Im, z2.Im$); **end**;
function *IsEqWithInt*(**const** z : *RComplex*;
 n : *longint*): *Boolean*;
 var s : *string*;
 begin *Str*(n, s); *IsEqWithInt* \leftarrow ($z.Im.Num = \text{'0'}$) \wedge ($z.Re.Num = s$) \wedge ($z.Re.Den = \text{'1'}$); **end**;

282. “Inequalities”. We “induce” the binary relations $<$ and \geq on the subset $\{q + i0 \mid q \in \mathbf{Q}\} \subseteq \mathbf{C}$. Again, what we said earlier about *RationalGT* being badly named holds for *IsRationalGT* being badly named as well.

\langle Predicate declarations for arbitrary-precision arithmetic 278 $\rangle + \equiv$
function *IsRationalLE*(**const** $z1, z2$: *RComplex*): *Boolean*;
function *IsRationalGT*(**const** $z1, z2$: *RComplex*): *Boolean*;

283. \langle Complex-rational arbitrary-precision arithmetic 279 $\rangle + \equiv$
function *IsRationalLE*(**const** $z1, z2$: *RComplex*): *Boolean*;
 begin *IsRationalLE* \leftarrow ($z1.Im.Num = \text{'0'}$) \wedge ($z2.Im.Num = \text{'0'}$) \wedge *RationalLE*($z1.Re, z2.Re$); **end**;
function *IsRationalGT*(**const** $z1, z2$: *RComplex*): *Boolean*;
 begin *IsRationalGT* \leftarrow ($z1.Im.Num = \text{'0'}$) \wedge ($z2.Im.Num = \text{'0'}$) \wedge *RationalGT*($z1.Re, z2.Re$); **end**;

Subsection 9.3.1. Arithmetic operations

284. Converting integers to complex numbers. We have a function to convert an integer $x \in \mathbf{Z}$ to be the complex number $(x/1) + i(0/1) \in \mathbf{C}$.

\langle Declare public complex-valued arbitrary precision arithmetic 284 $\rangle \equiv$
function *IntToComplex*(x : *integer*): *RComplex*;

See also sections 286, 288, 290, 292, 295, 298, and 300.

This code is used in section 198.

285. \langle Complex-rational arbitrary-precision arithmetic 279 $\rangle + \equiv$
function *IntToComplex*(x : *integer*): *RComplex*;
 var $lRes$: *RComplex*;
 begin $lRes \leftarrow COne$; $lRes.Re.Num \leftarrow IntToStr(x)$; *IntToComplex* $\leftarrow lRes$;
 end;

286. Adding complex numbers. We compute the sum of $(x_1 + iy_1)$ and $x_2 + iy_2$ to be $(x_1 + x_2) + i(y_1 + y_2)$.

\langle Declare public complex-valued arbitrary precision arithmetic 284 $\rangle + \equiv$
function *ComplexAdd*(**const** $z1, z2$: *RComplex*): *RComplex*;

287. \langle Complex-rational arbitrary-precision arithmetic 279 $\rangle + \equiv$
function *ComplexAdd*(**const** $z1, z2$: *RComplex*): *RComplex*;
 var $lRes$: *RComplex*;
 begin $lRes.Re \leftarrow RationalAdd(z1.Re, z2.Re)$; $lRes.Im \leftarrow RationalAdd(z1.Im, z2.Im)$;
 if.def (*CH_REPORT*) *CHReport.Out_NumReq3*(*rqRealAdd*, $z1, z2, lRes$); **endif**
 ComplexAdd $\leftarrow lRes$;
 end ;

288. Subtracting complex numbers. We find the difference of complex numbers componentwise.

⟨ Declare public complex-valued arbitrary precision arithmetic 284 ⟩ +≡

function *ComplexSub*(**const** *z1*, *z2*: *RComplex*): *RComplex*;

289. ⟨ Complex-rational arbitrary-precision arithmetic 279 ⟩ +≡

function *ComplexSub*(**const** *z1*, *z2*: *RComplex*): *RComplex*;

var *lRes*: *RComplex*;

begin *lRes.Re* ← *RationalSub*(*z1.Re*, *z2.Re*); *lRes.Im* ← *RationalSub*(*z1.Im*, *z2.Im*);

if_def (*CH-REPORT*) *CHReport.Out_NumReq3*(*rqRealDiff*, *z1*, *z2*, *lRes*); **end_if**

ComplexSub ← *lRes*;

end ;

290. Negating complex numbers. We negate a complex number $-z$ by negating its real and imaginary parts.

⟨ Declare public complex-valued arbitrary precision arithmetic 284 ⟩ +≡

function *ComplexNeg*(**const** *z*: *RComplex*): *RComplex*;

291. ⟨ Complex-rational arbitrary-precision arithmetic 279 ⟩ +≡

function *ComplexNeg*(**const** *z*: *RComplex*): *RComplex*;

var *lRes*: *RComplex*;

begin *lRes.Re* ← *RationalNeg*(*z.Re*); *lRes.Im* ← *RationalNeg*(*z.Im*);

if_def (*CH-REPORT*) *CHReport.Out_NumReq2*(*rqRealNeg*, *z*, *lRes*); **end_if**

ComplexNeg ← *lRes*;

end ;

292. Multiplying complex numbers. We use the usual formula

$$(x_1 + iy_1)(x_2 + iy_2) = (x_1x_2 - y_1y_2) + i(x_1y_2 + y_1x_2).$$

⟨ Declare public complex-valued arbitrary precision arithmetic 284 ⟩ +≡

function *ComplexMult*(**const** *z1*, *z2*: *RComplex*): *RComplex*;

293. ⟨ Complex-rational arbitrary-precision arithmetic 279 ⟩ +≡

function *ComplexMult*(**const** *z1*, *z2*: *RComplex*): *RComplex*;

var *lRes*: *RComplex*;

begin if *IsEqWithInt*(*z1*, -1) **then** *ComplexMult* ← *ComplexNeg*(*z2*)

else if *IsEqWithInt*(*z2*, -1) **then** *ComplexMult* ← *ComplexNeg*(*z1*)

else ⟨ Calculate the usual multiplication of complex numbers 294 ⟩;

end;

294. ⟨ Calculate the usual multiplication of complex numbers 294 ⟩ ≡

begin *lRes.Re* ← *RationalSub*(*RationalMult*(*z1.Re*, *z2.Re*), *RationalMult*(*z1.Im*, *z2.Im*));

lRes.Im ← *RationalAdd*(*RationalMult*(*z1.Re*, *z2.Im*), *RationalMult*(*z1.Im*, *z2.Re*));

ComplexMult ← *lRes*;

if_def (*CH-REPORT*) *CHReport.Out_NumReq3*(*rqRealMult*, *z1*, *z2*, *lRes*); **end_if**

end

This code is used in section 293.

295. Dividing complex numbers. We recall

$$\frac{x_1 + iy_1}{x_2 + iy_2} = \frac{(x_1 + iy_1)(x_2 - iy_2)}{x_2^2 + y_2^2}$$

This is the case for nonzero $z_2 \neq 0$. When we try to divide $z_1/0$, we return 0.

⟨ Declare public complex-valued arbitrary precision arithmetic 284 ⟩ +≡
function *ComplexDiv*(**const** $z1, z2: RComplex$): *RComplex*;

296. ⟨ Complex-rational arbitrary-precision arithmetic 279 ⟩ +≡
function *ComplexDiv*(**const** $z1, z2: RComplex$): *RComplex*;
 var $lDenom: Rational; lRes: RComplex$;
 begin $lRes \leftarrow CZero$;
 with $z2$ **do** $lDenom \leftarrow RationalAdd(RationalMult(Re, Re), RationalMult(Im, Im))$;
 if $lDenom.Num \neq '0'$ **then** ⟨ Calculate quotient for nonzero divisor 297 ⟩;
 $ComplexDiv \leftarrow lRes$;
 end;

297. ⟨ Calculate quotient for nonzero divisor 297 ⟩ ≡
 begin
 $lRes.Re \leftarrow RationalDiv(RationalAdd(RationalMult($z1.Re, z2.Re$), $RationalMult($z1.Im, z2.Im$), $lDenom$))$;
 $lRes.Im \leftarrow RationalDiv(RationalSub(RationalMult($z1.Im, z2.Re$), $RationalMult($z1.Re, z2.Im$), $lDenom$))$;
 if_def (*CH_REPORT*) *CHReport.Out_NumReq3*(*rqRealDiv*, $z1, z2, lRes$); **end_if**
 end$$

This code is used in section 296.

298. Inverting complex numbers. We can now calculate z^{-1} as just $1/z$.

⟨ Declare public complex-valued arbitrary precision arithmetic 284 ⟩ +≡
function *ComplexInv*(**const** $z: RComplex$): *RComplex*;

299. ⟨ Complex-rational arbitrary-precision arithmetic 279 ⟩ +≡
function *ComplexInv*(**const** $z: RComplex$): *RComplex*;
 begin $ComplexInv \leftarrow ComplexDiv(COne, z)$; **end**;

300. Norm of complex numbers. The “norm” or *modulus* for a complex number is just the sum of the square of its components (well, the squareroot of this sum).

⟨ Declare public complex-valued arbitrary precision arithmetic 284 ⟩ +≡
function *ComplexNorm*(**const** $z: RComplex$): *Rational*;

301. ⟨ Complex-rational arbitrary-precision arithmetic 279 ⟩ +≡
function *ComplexNorm*(**const** $z: RComplex$): *Rational*;
 begin $ComplexNorm \leftarrow RationalAdd(RationalMult($Z.Re, Z.Re$), $RationalMult($Z.Im, Z.Im$))$; **end**;$

Section 9.4. COMPARISON FUNCTIONS

302. The remainder of `numbers.pas` defines functions which compares numbers. These must return a value in the set $\{-1, 0, +1\}$ as a PASCAL *integer*.

⟨ Declare public comparison operators for arbitrary-precision numbers 302 ⟩ \equiv

```
function CompareInt(X1, X2 : longint): integer;
function CompareIntStr(X1, X2 : string): integer;
```

See also section 304.

This code is used in section 198.

303. ⟨ Complex-rational arbitrary-precision arithmetic 279 ⟩ $+\equiv$

```
function CompareInt(X1, X2 : longint): integer;
  begin if X1 = X2 then CompareInt  $\leftarrow$  0
  else if X1 > X2 then CompareInt  $\leftarrow$  1
  else CompareInt  $\leftarrow$  -1;
  end;
function CompareIntStr(X1, X2 : string): integer;
  begin if X1 = X2 then CompareIntStr  $\leftarrow$  0
  else if gt(X1, X2) then CompareIntStr  $\leftarrow$  1
  else CompareIntStr  $\leftarrow$  -1;
  end;
```

304. There is also a function to “compare” complex numbers. This treats a complex number

$$z = \frac{n_1}{d_1} + i \frac{n_2}{d_2}$$

as a tuple (n_1, d_1, n_2, d_2) then uses lexicographic ordering based on the components.

⟨ Declare public comparison operators for arbitrary-precision numbers 302 ⟩ $+\equiv$

```
function CompareComplex(const z1, z2 : RComplex): integer;
```

305. ⟨ Complex-rational arbitrary-precision arithmetic 279 ⟩ $+\equiv$

```
function CompareComplex(const z1, z2 : RComplex): integer;
  var lnt : integer;
  begin lnt  $\leftarrow$  CompareIntStr(z1.Re.Num, z2.Re.Num);
  if lnt  $\neq$  0 then
    begin CompareComplex  $\leftarrow$  lnt; exit end;
  lnt  $\leftarrow$  CompareIntStr(z1.Re.Den, z2.Re.Den);
  if lnt  $\neq$  0 then
    begin CompareComplex  $\leftarrow$  lnt; exit end;
  lnt  $\leftarrow$  CompareIntStr(z1.Im.Num, z2.Im.Num);
  if lnt  $\neq$  0 then
    begin CompareComplex  $\leftarrow$  lnt; exit end;
  CompareComplex  $\leftarrow$  CompareIntStr(z1.Im.Den, z2.Im.Den);
  end;
```

File 10

Mizar Objects and Data Structures

306. This is one of the largest files in Mizar (it clocks in at 6594 lines of code). Its interface consists of 552 lines alone (roughly 1/13 of the file).

We should remind the reader PASCAL has “typed pointers”, meaning an object with type $\uparrow Foo$ is a pointer to a *Foo* object. We lookup the object for a pointer p : $\uparrow Foo$ by dereferencing it as $p\uparrow$. If $foo: Foo$ is an instance, we can have p point to it by writing $p \leftarrow @foo$.

Further, it is idiomatic PASCAL to have for each type *Foo* a pointer type $PFoo = \uparrow Foo$.

307. We will refer to “some data allocated in memory” as an “**Object**”. Alexander Stepanov and Paul McJones’s *Elements of Programming* (elementsofprogramming.com) discuss object-oriented programming from a rather baroque philosophical perspective, which the reader may find enjoyable.

```

< mobjects.pas 307 > ≡
  < GNU License 4 >
unit mobjects;
interface
  uses numbers;
  < Public interface for mobjects.pas 310 >
implementation
  mdebug uses info; end_mdebug
  < Implementation for mobjects.pas 308 >
end .

```

308. We have an error method for situations when a method is not implemented, for example when there is no ordering operator when the user invokes *MSortedCollection.Compare* (§430).

```

< Implementation for mobjects.pas 308 > ≡
procedure Abstract1;
  begin RunError(211);
end;

```

See also section 309.

This code is used in section 307.

309. The “roadmap” for the data structures implemented in this library may be summed up loosely as: we introduce a base “object” class, then we introduce a family of collections, then we conclude with classes for sequences and partial functions.

⟨Implementation for `mobjects.pas` 308⟩ +≡
 ⟨ *MObject* implementation 313⟩
 ⟨ *MStrObj* implementation 318⟩
 ⟨ *MList* implementation 324⟩ { start of collections classes }

 ⟨ Stacked object implementation 450⟩
 ⟨ String list implementation 454⟩
 ⟨ Int relation implementation 498⟩ { start of partial functions }
 ⟨ Partial integer function implementation 507⟩
 ⟨ *NatFunc* implementation 529⟩
 ⟨ *NatSeq* implementation 548⟩
 ⟨ *IntSequence* implementation 553⟩
 ⟨ *IntSet* Implementation 569⟩
 ⟨ Partial Binary integer Functions 580⟩
 ⟨ Partial integers to Pair of integers Functions 598⟩

310. Constant parameters. Note that the *SizeOf(Pointer)* is 4 on 32-bit machines, and 8 on 64-bit machines. Since

$$2\,000\,000 = 250\,000 \times 8$$

this means that a collection can have at most 250,000 items on a 64-bit machine (whereas on a 32-bit machine they can have twice that). Perhaps a better approach would be to fix *MaxSize* to a fixed value, then *MaxSize* would be assigned *MaxCollectionSize* * *SizeOf(Pointer)*.

⟨Public interface for `mobjects.pas` 310⟩ ≡
const { Maximum MCollection size }
MaxSize = 2000000;
MaxCollectionSize = *MaxSize* **div** *SizeOf(Pointer)*;
MaxListSize = *MaxSize* **div** (*SizeOf(Pointer)* * 2); { Maximum MStringList size }
MaxIntegerListSize = *MaxSize* **div** (*SizeOf(integer)*); { Maximum IntegerList size }
 { MCollection error codes }
coIndexError = -1; { Index out of range }
coOverflow = -2; { Overflow }
coConsistentError = -3;
coDuplicate = -5; { Duplicate }
coSortedListError = -6;
coIndexExtError = -7;

See also sections 311, 312, 317, 321, 322, 349, 370, 387, 409, 423, 428, 437, 441, 449, 451, 452, 485, 486, 497, 506, 528, 547, 552, 568, 579, 597, and 611.

This code is used in section 307.

311. Type aliases.

⟨Public interface for `mobjects.pas` 310⟩ +≡

type {String pointers}

PString = ↑*ShortString*; { *ShortString* = *String*[255] }

{ Character set type }

PCharSet = ↑*TCharSet*;

TCharSet = **set of** *char*;

{ General arrays }

PByteArray = ↑*TByteArray*;

TByteArray = **array** [0 .. 32767] **of** *byte*; { $32767 = 2^{15} - 1$ }

PWordArray = ↑*TWordArray*;

TWordArray = **array** [0 .. 16383] **of** *word*; { $16383 = 2^{14} - 1$ }

Section 10.1. BASE OBJECT

312. Object-oriented PASCAL is a bit crufty (like all Object-oriented ALGOL-descended languages).

The base *MObject* “class” has a constructor, destructor, a clone function named *CopyObject*, and a “move” function called *MCopy*.

```

⟨ Public interface for mobjects.pas 310 ⟩ +≡
  { MObject base object }
  PObject = ↑MObject;
  ObjectPtr = PObject;
  MObject = object
    constructor Init;
    procedure Free; { unused }
    destructor Done; virtual;
    function CopyObject: PObject;
    function MCopy: PObject; virtual;
  end ;

```

313. Note that the *VER70* conditional compilation only plays a role here, in the constructor *MObject.Init*. And nowhere else.

The constructor will initialize the memory allocated for the *MObject* to be zero. This is true when *VER70* is not defined, too, because the Free PASCAL compiler will allocate 1 word for the virtual methods table and 1 word for the data (“self”) and the default constructor (“*fpc_help_constructor*”) for Free PASCAL initializes the memory allocated with zeros.

```

⟨ MObject implementation 313 ⟩ ≡
  { MObject }
constructor MObject.Init;
  @{@&$IFDEF VER70@}
  type Image = record Link: word;
    Data: record
      end;
    end;
  @{@&$ENDIF@}
  begin
    @{@&$IFDEF VER70@} FillChar(Image(Self).Data, SizeOf(Self) - SizeOf(MObject), 0);
    @{@&$ENDIF@}
  end;

```

This code is used in section 309.

314. Destructor. The destructor is, well, what C++ programmers would call an “abstract method”.

The *MObject.Free* procedure frees all the memory allocated to the caller. It isn’t used anywhere.

```

procedure MObject.Free; { unused }
  begin Dispose(PObject(@Self), Done); end;
destructor MObject.Done;
  begin end;

```

315. Copying an object allocates new memory using the Free PASCAL *GetMem* function, then *copies* the contents of the caller to the new region. The *move* primitive function is poorly named (blame Borland): it is a copy function.

It then returns a pointer to the newly allocated object.

Note that this function is used in only two places: once in *MCopy*, and later in *MList.MCopy* (§329).

```
function MObject.CopyObject: PObject;
var lObject: PObject;
begin GetMem(lObject, SizeOf(Self));
      Move(Self, lObject↑, SizeOf(Self));
      CopyObject ← lObject;
end;
```

316. The virtual method for copying Mizar objects can be overridden by subclasses. But the default method is just *CopyObject*.

```
function MObject.MCopy: PObject;
begin MCopy ← CopyObject; end;
```

Section 10.2. MIZAR STRING OBJECT

317. We want to treat strings as *MObjects*, and the way object-oriented programming handles this situation is to create a subclass consisting of just a string field. This amounts to a “wrapper class”.

```

⟨ Public interface for mobjects.pas 310 ⟩ +≡
  { Specyfics objects based on MObjects for collections }
  PStr = ↑MStrObj;
  MStrPtr = PStr;
  MStrObj = object (MObject)
    fStr: string;
    constructor Init(const aStr: string);
  end ;

```

318. Constructor. The constructor for a string object expects a string, and simply initializes its contents to the given string.

```

⟨ MStrObj implementation 318 ⟩ ≡
  { Specyfics objects based on MObjects for collections }
constructor MStrObj.Init(const aStr: string);
  begin fStr ← aStr; end;

```

This code is used in section 309.

Section 10.3. MIZAR LIST

319. A *MList* is a dynamic array data structure, which represents a list using an array. We reserve an array whose length is referred to as its “**Capacity**” in the literature.

Not all of the underlying array is used by the user. The number of entries which are used by the dynamic array contents is referred to as its “**Logical Size**” (or just its *Size*) in the literature.

When the dynamic array is filled, it “grows”; i.e., it allocates a new array that’s larger, and copies over the contents of its old array, then frees the old array. The growth factor is controlled by the *GrowLimit*(*oldSize*) value.

320. Review of pointers in Pascal. We have a few parameters needed for collections. Remember, if T is a type, then $\uparrow T$ is the type of pointers to T objects. If we want to have a pointer without referring to the *type* of the object referenced, we can use *Pointer*.

The @ operator is the “address of” operator. When setting a pointer p to point to something Foo , we have $p \leftarrow @Foo$.

The \uparrow operator is the “dereferencing” operator which is appended to a pointer identifier. When we want to update the object referenced by a pointer p , we have $p\uparrow \leftarrow newValue$.

321. \langle Public interface for `mobjects.pas` 310 $\rangle + \equiv$
 { MCollection types }
 $PItemList = \uparrow MItemList$;
 $MItemList = \text{array } [0 \dots MaxCollectionSize - 1] \text{ of } Pointer$;

322. A *MList* object is known as a dynamic array. Java programmers would know that as an `ArrayList`.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  { MList object }
  PList = ↑MList;
  MListPtr = PList;
  MList = object (MObject)
    Items: PItemList; { Contents of dynamic array }
    Count: integer; { Logical size of dynamic array }
    Limit: integer; { Capacity of dynamic array }
    constructor Init(ALimit : integer);
    constructor MoveList(var aAnother : MList);
    constructor CopyList(var aAnother : MList);
    destructor Done; virtual;
    function MCopy: PObject; virtual;
    procedure ListError(aCode, aInfo : integer); virtual;
    function At(Index : integer): Pointer;
    function Last: Pointer;
    procedure Insert(aItem : Pointer); virtual;
    procedure AtInsert(aIndex : integer; aItem : Pointer); virtual;
    procedure InsertList(var aAnother : MList); virtual;
    function GetObject(aIndex : integer): Pointer; virtual;
    function IndexOf(aItem : Pointer): integer; virtual;
    procedure DeleteAll; virtual;
    procedure FreeItem(Item : Pointer); virtual;
    procedure FreeAll; virtual;
    procedure FreeItemsFrom(aIndex : integer); virtual;
    procedure Pack; virtual;
    procedure SetLimit(ALimit : integer); virtual;
    procedure AppendTo(var fAnother : MList); virtual;
    procedure TransferItems(var fAnother : MList); virtual;
    procedure CopyItems(var fOrigin : MList); virtual;
end ;

```

323. It's worth pointing out that an *MList* does not “own” the items in it, in the sense that: when we delete an *MList* instance, we do not need to delete each item in it.

324. Growth factor. How quickly an Dynamic Array grows is a subject of debate. Just for a table of the growth factors:

Implementation	Growth Factor
Java's ArrayList	$3/2 = 1.5$
Microsoft's Visual C++	$3/2 = 1.5$
Facebook folly/FBVector	$3/2 = 1.5$
Unreal Engine's TArray	$n + ((3n) \gg 3) \sim 1.375$
Python PyListObject	$n + (n \gg 3) \sim 1.125$
Go slices	between 1.25 and 2
Gnu C++	2
Clang	2
Rust's Vec	2
Nim sequences	2
SBCL vectors	2
C#	2

The *MList* uses a staggered growth factor, specifically something like $s(n) \leftarrow s(n) + \text{GrowLimit}(s(n))$. The sequence of Dynamic Array size would be:

$$s(n) = (0, 4, 8, 12, 28, 44, 60, 76, \dots)$$

followed by $s(n+1) \leftarrow (5/4)s(n)$. I am not sure this is optimal, but I have no better solution.

CAUTION: If the memory allocator uses a first-fit allocation, then growth factors like $\alpha \geq 2$ can cause dynamic array expansion to run out of memory even though a significant amount of memory may still be available. For a discussion about this point, see:

- <http://www.gahcep.com/cpp-internals-stl-vector-part-1/>

The reader wondering what strategy Free PASCAL uses should consult §8.4.1 of the “Free PASCAL Programmer’s Guide” ([eprint](#)).

It seems that a growth factor $\alpha \leq \varphi = (1 + \sqrt{5})/2$ must be not bigger than the golden ratio. To see this, we need a dyanmic array of size S to have its first growth to allocate αS , then frees up the S bytes from the pre-growth allocation. The second allocation needs $\alpha^2 S$ bytes. Observe the first two allocations requires $S + \alpha S$ bytes available. Now suppose we want this to be able to fit into the newly freed space,

$$\alpha^2 S \leq S + \alpha S$$

which means

$$\alpha^2 - \alpha + 1 \leq 0$$

or (requiring $\alpha > 0$)

$$\alpha \leq \varphi = \frac{1 + \sqrt{5}}{2}.$$

When this fails to hold, a first-fit allocation could run out of memory.

$\langle MList \text{ implementation } 324 \rangle \equiv$

{ Simple Collection }

function *GrowLimit*(*aLimit* : integer): integer;

begin *GrowLimit* \leftarrow 4;

if *aLimit* > 64 **then** *GrowLimit* \leftarrow *aLimit* **div** 4

else if *aLimit* > 8 **then** *GrowLimit* \leftarrow 16;

end;

This code is used in section 309.

325. Constructor. The constructor creates an empty list. The initial capacity and initial size are both set to zero.

```
constructor MList.Init(aLimit : integer);
  begin MObject.Init; Items  $\leftarrow$  nil; Count  $\leftarrow$  0; Limit  $\leftarrow$  0; SetLimit(aLimit); end;
```

326. Moving a list into the caller. Since an *MList* does not own its contents, moving its contents around amounts to updating pointers. The *DeleteAll* (§338) method just updates the capacity of the caller to zero, it does not free anything from memory.

```
constructor MList.MoveList(var aAnother : MList);
  begin MObject.Init;
    Count  $\leftarrow$  aAnother.Count; Limit  $\leftarrow$  aAnother.Limit; Items  $\leftarrow$  aAnother.Items; { move }
    aAnother.DeleteAll; aAnother.Limit  $\leftarrow$  0; aAnother.Items  $\leftarrow$  nil; { delete aAnother }
  end;
```

327. Copying the contents of *aAnother* list into the current list will essentially reinitialize the current list, the insert all items from the other list into the current list using *InsertList* (§334).

```
constructor MList.CopyList(var aAnother : MList);
  begin MObject.Init; Items  $\leftarrow$  nil; Count  $\leftarrow$  0; Limit  $\leftarrow$  0; { initialize }
    SetLimit(aAnother.Limit); InsertList(aAnother);
  end;
```

328. A list is “done” frees all items in the list, sets the limit to zero, and then invokes the superclass’s *Done* method.

```
destructor MList.Done;
  begin FreeAll; SetLimit(0); inherited Done; end;
```

329. We override the *MObject.MCopy* method (§316). This will copy the base object using *CopyObject* (§315), allocate a new array of pointers, copy over the contents of the caller, and then returns the new list.

Importantly, this *will* allocate new objects on the heap, duplicating every entry in the caller *and* the caller’s data (capacity and size).

```
function MList.MCopy: PObject;
  var lList: PObject; i: integer;
  begin lList  $\leftarrow$  CopyObject; GetMem(PList(lList) $\uparrow$ .Items, Self.Limit * SizeOf(Pointer));
  for i  $\leftarrow$  0 to Self.Count - 1 do PList(lList) $\uparrow$ .Items $\uparrow$ [i]  $\leftarrow$  PObject(Self.Items $\uparrow$ [i]) $\uparrow$ .MCopy;
    MCopy  $\leftarrow$  lList;
  end;
```

330. This is the same as *MList.GetObject* (§335), and I am not sure why we have two versions of the same function.

```
function MList.At(Index : integer): Pointer;
  begin if (Index < 0)  $\vee$  (Index  $\geq$  Count) then
    begin ListError(coIndexError, 0); At  $\leftarrow$  nil; end
  else At  $\leftarrow$  Items $\uparrow$ [Index];
  end;
```

331. The *MList.Count* tracks the number of allocated items. So the last item would be located at *MList.Count* - 1 (since we count with zero offset).

```
function MList.Last: Pointer;
  begin Last  $\leftarrow$  At(Count - 1); end;
```

332. Inserting an item into a list requires checking there's enough free space to the list, then sets the first spot to the item.

```
procedure MList.Insert(aItem : Pointer);
  begin if Limit = Count then SetLimit(Limit + GrowLimit(Limit)); { ensure capacity }
  Items↑[Count] ← aItem; inc(Count);
end;
```

333. If we want to insert a pointer *at a specific index*, then we proceed as follows:

- (1) Check if the index is negative. If so, then we should flag an error using *ListError*, and exit.
- (2) Check if the index is larger than the logical size of the dynamic array; if so, then we grow the dynamic array using *SetLimit*

PUZZLE: What happens if the user calls *AtInsert*(*caller.Count* − *n*, *object*)? The code will set every pointer in *Items*[*Caller.Count* − *n* .. *Caller.Count* − 1] to **nil**, which seems buggy.

SOLUTION: The *SetLimit* method *does not* update the *Count* field of the caller, so the problem just stated will never happen.

```
procedure MList.AtInsert(aIndex : integer; aItem : Pointer);
  var i, lLimit: integer;
  begin if aIndex < 0 then
    begin ListError(coIndexError, 0); exit;
    end;
  if (aIndex ≥ Limit) ∨ ((aIndex = Count) ∧ (Limit = Count)) then { ensure capacity }
    begin lLimit ← Limit + GrowLimit(Limit);
    while aIndex + 1 > lLimit do lLimit ← lLimit + GrowLimit(lLimit);
    SetLimit(lLimit); { Copy contents }
    end;
  for i ← Count to aIndex − 1 do Items↑[i] ← nil; { fill new entries as nil }
  Items↑[aIndex] ← aItem; { set the entry at aIndex to the pointer }
  if aIndex ≥ Count then Count ← aIndex + 1; { update logical size, if necessary }
end;
```

334. When we insert *aAnother* list into the current list, we simply iterate through all the other list's items, and insert (a copy of the pointer to) each one into the current list. This should leave *aAnother* list unmodified.

Observe that this has, for each item in the argument supplied, the caller *Insert* a pointer to a copy of each item. That is to say, the caller *pushes* a new item to the end of the caller's contents.

```
procedure MList.InsertList(var aAnother : MList);
  var i: integer;
  begin for i ← 0 to pred(aAnother.Count) do Insert(PObject(aAnother.Items↑[i])↑.MCopy);
  end;
```

335. Given an index, find the item located there. Well, the pointer to the object. When the index is illegal (out of bounds or negative), then flag an error and return **nil**. Otherwise return the pointer located at the index.

```
function MList.GetObject(aIndex : integer): Pointer;
  begin if (aIndex < 0) ∨ (aIndex ≥ Count) then
    begin ListError(coIndexError, 0); GetObject ← nil; end
  else GetObject ← Items↑[aIndex];
  end;
```

336. We have a default error code for lists.

```
procedure MList.ListError(aCode, aInfo : integer);
begin RunError(212 - aCode); end;
```

337. Looking for the index of an item requires iterating through each item of the list, until we find the needle in the haystack. Once found, we return the index for the needle.

If the needle is not in the haystack, return -1 .

Note: this uses pointer comparison, so it will not compare the *contents* of the object for equality.

```
function MList.IndexOf(aItem : Pointer): integer;
var i: integer;
begin IndexOf  $\leftarrow -1$ ;
for i  $\leftarrow 0$  to pred(Count) do
  if aItem = Items $\uparrow$ [i] then
    begin IndexOf  $\leftarrow i$ ; break end
end;
```

338. Deleting all items from a list simply updates the list's logical size (i.e., *Count*) to zero. Important contracts which hold about this:

- This will not alter the underlying array allocated for the dynamic array.
- This will not free any allocated objects from memory.

```
procedure MList.DeleteAll;
begin Count  $\leftarrow 0$ ; end;
```

339. Freeing a single item will invoke PASCAL's primitive *Dispose* function (which frees up the memory in heap). This is a helper function to avoid accidentally invoking *Dispose*(*PObject*(**nil**), *Done*) which would throw errors.

[[This method appears to be used only by subclasses of *MList*, so I think this should be a protected method.]]

```
procedure MList.FreeItem(Item : Pointer);
begin if Item  $\neq$  nil then Dispose(PObject(Item), Done);
end;
```

340. We delegate all the heavy work of *FreeAll* to *FreeItemsFrom*.

```
procedure MList.FreeAll;
begin FreeItemsFrom(0); end;
```

341. We can iterate through a list from a start index, freeing the rest of the list starting from *aIndex*. Remember, the data structure for *MList* consists of an *MObject* extended with its capacity, logical size, and a *pointer* to the array on the heap. When freeing an item from the array, we dereference the pointer to look up item *I* in the array.

```
procedure MList.FreeItemsFrom(aIndex : integer);
var I: integer;
begin for I  $\leftarrow$  Count - 1 downto aIndex do FreeItem(Items $\uparrow$ [I]);
  Count  $\leftarrow$  aIndex;
end;
```

342. If an item has become **nil** in the list, we should shift the rest of the list down. Basically, in Lisp, if `null (cadr 1)`, then `setf 1 (cdr 1)`.

Care must be taken to iterate over the items in the list. Shifting items down by one item requires iterating over k from i to $Count - 2$ (because the maximum index is $Count - 1$ due to zero offset indexing).

Once we have shifted everything down, we decrement the logical size of the dynamic array.

```

procedure MList.Pack;
  var  $i, k$ : integer;
  begin for  $i \leftarrow Count - 1$  downto 0 do
    if  $Items \uparrow [i] = \mathbf{nil}$  then
      begin for  $k \leftarrow i$  to  $Count - 2$  do  $Items \uparrow [k] \leftarrow Items \uparrow [k + 1]$ ;
         $dec(Count)$ ;
      end;
    end;
  end;

```

343. Growing a list handles a few edgecases:

- (1) If the new limit is *smaller* than the existing limit, then just set the new limit equal to the existing limit.
- (2) If the new limit is *larger* than the maximum limit, then just set the new limit equal to the maximum limit.
- (3) If the new limit is not equal to the existing limit, then we have the “standard situation”.
 - (i) When the new limit is zero, simply set the pointer to the item list to **nil**
 - (ii) Otherwise (for a new limit which is a nonzero number), allocate a new chunk of memory for the number of pointers needed, then move them. Be sure to free up the pointers, and update the variables.

```

procedure MList.SetLimit( $ALimit$  : integer);
  var  $lItems$ : PItemList;
  begin  $\langle \text{Ensure } Count \leq ALimit \leq MaxCollectionSize \text{ 344} \rangle$ ;
  if  $ALimit \neq Limit$  then
    begin if  $ALimit = 0$  then  $lItems \leftarrow \mathbf{nil}$ 
      else  $\langle \text{Allocate a new array, and copy old contents into new array 345} \rangle$ ;
      if  $Limit \neq 0$  then  $FreeMem(Items, Limit * SizeOf(Pointer))$ ;
       $Items \leftarrow lItems$ ;  $Limit \leftarrow ALimit$ ;
    end;
  end;

```

```

344.  $\langle \text{Ensure } Count \leq ALimit \leq MaxCollectionSize \text{ 344} \rangle \equiv$ 
  if  $ALimit < Count$  then  $ALimit \leftarrow Count$ ;
  if  $ALimit > MaxCollectionSize$  then  $ALimit \leftarrow MaxCollectionSize$ 

```

This code is used in sections 343 and 419.

```

345.  $\langle \text{Allocate a new array, and copy old contents into new array 345} \rangle \equiv$ 
  begin  $GetMem(lItems, ALimit * SizeOf(Pointer))$ ;
  if  $((Count \neq 0) \wedge (Items \neq \mathbf{nil}))$  then  $Move(Items \uparrow, lItems \uparrow, Count * SizeOf(Pointer))$ ;
  end

```

This code is used in section 343.

346. Appending another list to the current list will expand the current list to support the new items, insert the other list's items at the end of the current list, and then free the other list from memory.

```
procedure MList.AppendTo(var fAnother : MList);
  var k: integer;
  begin SetLimit(Count + fAnother.Count);
  for k  $\leftarrow$  0 to fAnother.Count - 1 do Insert(fAnother.Items $\uparrow$ [k]);
  fAnother.DeleteAll; fAnother.Done;
end;
```

347. There is a comment in Polish at the beginning of this function stating “Przeznaczeniem tej procedury jest uzycie jej w konstruktorach *Move*, ktore wykonuja jakgdyby pelna instrukcje przypisania (razem z VMTP)” which Google translates as “The purpose of this procedure is to be used in *Move* constructors, which execute a full assignment statement (including VMTP [virtual method table pointer]).”

There is also another comment in Polish, “Nie wolno uzyc *SetLimit*, bo rozdysponuje Items” which I translated into English and kept inline (“You cannot use *SetLimit* because it will distribute the Items”).

The semantics of *Object* \leftarrow *Object* will *copy* the right-hand side to the left-hand side.

```
procedure MList.TransferItems(var fAnother : MList);
  begin Self  $\leftarrow$  fAnother; { copy contents of fAnother over to Self }
  fAnother.DeleteAll; fAnother.Limit  $\leftarrow$  0; fAnother.Items  $\leftarrow$  nil;
  { You cannot use SetLimit because it will distribute the Items. }
end;
```

348. Copying items from a list simply loops through the original list, inserting them into the caller.

```
procedure MList.CopyItems(var fOrigin : MList);
  var i: integer;
  begin for i  $\leftarrow$  0 to fOrigin.Count - 1 do Insert(PObject(fOrigin.Items $\uparrow$ [i]) $\uparrow$ .CopyObject);
end;
```

Section 10.4. MIZAR COLLECTION CLASS

349. Curiously, the “Collection” class extends the “List” class, which surprises me. This will change the growth rate from $s(n+1) = s(n) + \text{GrowLimit}(s(n))$ to be

$$s(n+1) = s(n) + \text{GrowLimit}(\Delta + s(n))$$

where $\Delta \geq 0$ is a field of the Collection object. When we move an *MList* into an *MCollection*, we have $\Delta \leftarrow 2$ be the default value.

Fig. 1. UML class diagram for MCollection class.

```

<Public interface for mobjects.pas 310> +≡
  { MCollection object }
  PCollection = ↑MCollection;
  MCollection = object (MList)
    Delta: integer;
    constructor Init(ALimit, ADelta : integer);
    destructor Done; virtual;
    procedure AtDelete(Index : integer);
    procedure AtFree(Index : integer);
    procedure AtInsert(Index : integer; Item : Pointer); virtual;
    procedure AtPut(Index : integer; Item : Pointer);
    procedure Delete(Item : Pointer);
    procedure Free(Item : Pointer);
    procedure Insert(aItem : Pointer); virtual;
    procedure Pack; virtual;
    constructor MoveCollection(var fAnother : MCollection);
    constructor MoveList(var aAnother : MList);
    constructor CopyList(var aAnother : MList);
    constructor CopyCollection(var AAnother : MCollection);
    constructor Singleton(fSing : PObject; fDelta : integer);
    procedure Prune; virtual;
  end ;
  
```

350. Constructor. When constructing a new Collection, we allocate an array of the desired limit (using the *SetLimit* (§343) to handle this allocation).

[[We should have preconditions that $\Delta \geq 0$ and $ALimit \geq 0$, enforced by assertions.]]

```

<MCollection implementation 350> ≡
  { MCollection }
  constructor MCollection.Init(ALimit, ADelta : integer);
  begin MObject.Init; Items ← nil; Count ← 0; Limit ← 0; Delta ← ADelta; SetLimit(ALimit);
  end;
  
```

See also sections 351, 352, 355, 356, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, and 369.

This code is used in section 309.

351. Destructor. When the destructor for an *MCollection* is invoked, all the items are freed using *FreeAll* (§340).

```

⟨ MCollection implementation 350 ⟩ +≡
destructor MCollection.Done;
  begin FreeAll; SetLimit(0);
  end;

```

352. Delete entry at an index. When trying to delete an element at *Index*, we first check if the *Index* is within the bounds of the collection. If it's out of bounds, we invoke *ListError* and exit the function.

Otherwise, we shift everything in the collection down by one position to the left. This means the entry at the end of the collection (when the caller invokes this function) stays there, but the logical size of the caller decrements by one.

```

⟨ MCollection implementation 350 ⟩ +≡
procedure MCollection.AtDelete(Index : integer);
  var i: integer;
  begin ⟨ Check Index for MCollection is within bounds, raise an error if it's out of bounds 353 ⟩;
  ⟨ Shift entries of MCollection to the left by one 354 ⟩;
  dec(Count);
  end;

```

353. ⟨ Check *Index* for *MCollection* is within bounds, raise an error if it's out of bounds 353 ⟩ ≡
if (*Index* < 0) ∨ (*Index* ≥ *Count*) **then**
begin *ListError*(*coIndexError*, 0); *exit*;
end

This code is used in sections 352, 356, and 359.

354. ⟨ Shift entries of *MCollection* to the left by one 354 ⟩ ≡
if *Index* < *pred*(*Count*) **then**
for *i* ← *Index* **to** *Count* − 2 **do** *Items*↑[*i*] ← *Items*↑[*i* + 1]

This code is used in section 352.

355. Delete and free entry. If we want to also *free* an object in a collection, we store it in a temporary variable, then invoke *AtDelete*(*Index*) to update the collection, and finally *Free* the item.

```

⟨ MCollection implementation 350 ⟩ +≡
procedure MCollection.AtFree(Index : integer);
  var Item: Pointer;
  begin Item ← At(Index); AtDelete(Index); FreeItem(Item); end;

```

356. Inserting an entry at a specific location. Inserting an item at an *Index*, we first need to check if the position is within the bounds of the collection. If it's out of bounds, then flag a *ListError* and exit the function.

Otherwise, we check if the collection is at capacity ($Limit = Count$). If so, we try to expand the collection by *Delta* items. When *Delta* is zero, then raise an error and exit.

Now we are at the “default” case. Simply shift items starting at *Index* up by one. Then set the item at *Index* to be the new *Item*, and increment the count of the collection.

```

⟨ MCollection implementation 350 ⟩ +≡
procedure MCollection.AtInsert(Index : integer; Item : Pointer);
  begin ⟨ Check Index for MCollection is within bounds, raise an error if it's out of bounds 353 ⟩;
  ⟨ Ensure capacity of MCollection, raise coOverflow error if  $\Delta = 0$  357 ⟩;
  ⟨ Shift entries to the right by one 358 ⟩;
  Items↑[Index] ← Item; inc(Count);
end;

```

```

357. ⟨ Ensure capacity of MCollection, raise coOverflow error if  $\Delta = 0$  357 ⟩ ≡
  if Limit = Count then { grow the caller }
    begin if Delta = 0 then
      begin ListError(coOverflow, 0); exit;
      end;
      SetLimit(Limit + Delta);
    end

```

This code is used in section 356.

```

358. ⟨ Shift entries to the right by one 358 ⟩ ≡
  if Index ≠ Count then Move(Items↑[Index], Items↑[Index + 1], (Count - Index) * SizeOf(pointer))

```

This code is used in section 356.

359. Overwrite contents at index. We can insert a new item at a given index without shifting the collection. This overwrites the contents of the entry at *Index*, which just updates the pointer's value to the new *Item*.

[[This can cause a memory leak, if the object located at `\old(Items↑[Index])` is not “owned” by something else.]]

```

⟨ MCollection implementation 350 ⟩ +≡
procedure MCollection.AtPut(Index : integer; Item : Pointer);
  begin ⟨ Check Index for MCollection is within bounds, raise an error if it's out of bounds 353 ⟩;
  Items↑[Index] ← Item;
end;

```

360. Delete entry by pointer. Deleting an item finds the index of the item, then invokes *AtDelete* (§352) on that index.

```

⟨ MCollection implementation 350 ⟩ +≡
procedure MCollection.Delete(Item : Pointer);
  begin AtDelete(IndexOf(Item));
end;

```

361. Free element by pointer. Similarly, freeing an item is just *Delete*-ing the item (§360), then calling *FreeItem* (§339) on the pointer.

```

⟨ MCollection implementation 350 ⟩ +≡
procedure MCollection.Free(Item : Pointer);
  begin Delete(Item); FreeItem(Item);
end;

```

362. Add entry at end of collection. Inserting an item at the end of the collection.

```

⟨ MCollection implementation 350 ⟩ +≡
procedure MCollection.Insert(aItem : Pointer);
  begin AtInsert(Count, aItem);
end;

```

363. Delete nil pointers. We can also “fit” the collection by deleting all **nil** elements.

```

⟨ MCollection implementation 350 ⟩ +≡
procedure MCollection.Pack;
  var i: integer;
  begin for i ← pred(Count) downto 0 do
    if Items↑[i] = nil then AtDelete(i);
  end;

```

364. Move constructor. Move semantics for creating a new collection.

```

⟨ MCollection implementation 350 ⟩ +≡
constructor MCollection.MoveCollection(var fAnother : MCollection);
  begin Init(0, fAnother.Delta); TransferItems(fAnother) end;

```

365. Copy constructor. Cloning a collection will simply create an empty collection, the loop through *AAnother* inserting each item from the original collection into the newly minted collection.

```

⟨ MCollection implementation 350 ⟩ +≡
constructor MCollection.CopyCollection(var AAnother : MCollection);
  var i: integer;
  begin Init(AAnother.Limit, AAnother.Delta);
  for i ← 0 to AAnother.Count − 1 do Insert(aAnother.Items↑[i]);
end;

```

366. Singleton constructor. A singleton allocates as little as possible.

```

⟨ MCollection implementation 350 ⟩ +≡
constructor MCollection.Singleton(fSing : PObject; fDelta : integer);
  begin Init(2, fDelta); Insert(fSing) end;

```

367. Soft delete everything. Pruning a collection merely sets its limits to zero. It does not free the contents of the collection.

```

⟨ MCollection implementation 350 ⟩ +≡
procedure MCollection.Prune;
  begin SetLimit(0) end;

```

368. Move list into caller. Moving an *MList* into the caller uses PASCAL's inheritance semantics to invoke *MList.MoveList* and then sets the *Delta* to 2.

$\langle MCollection \text{ implementation } 350 \rangle + \equiv$
constructor *MCollection.MoveList*(**var** *aAnother* : *MList*);
 begin *inherited MoveList*(*aAnother*); *Delta* \leftarrow 2;
 end;

369. Copy constructor on a list. Copying a list invokes *MList.CopyList* on the collection, then sets *Delta* \leftarrow 2.

$\langle MCollection \text{ implementation } 350 \rangle + \equiv$
constructor *MCollection.CopyList*(**var** *aAnother* : *MList*);
 begin *inherited CopyList*(*aAnother*); *Delta* \leftarrow 2; **end**;

Section 10.5. SIMPLE STACKED (EXTENDIBLE) LISTS

370. This is used to track newly registered clusters in Mizar. We want to process or “digest” entries, and track which entries have been “digested” and which ones have not. So we partition the array into the first N entries (which have been “digested”) and then the remaining k “extendible” entries (which have yet to be “digested”).

We will eventually “digest” the extendible entries (by incrementing $N \leftarrow N+1$ and decrementing $k \leftarrow k-1$ until $k = 0$).

Fig. 2. UML class diagram for MExtList class.

```

⟨ Public interface for mobjects.pas 310 ⟩ +=
  { MExtList object }
  MExtListPtr = ↑ MExtList;
  MExtList = object (MList)
    fExtCount: integer;
    constructor Init(aLimit : integer);
    destructor Done; virtual;
    procedure Insert(aItem : Pointer); virtual;
    procedure Mark(var aIndex : integer); virtual;
    procedure FreeItemsFrom(aIndex : integer); virtual;
    procedure DeleteAll; virtual;
    procedure FreeAll; virtual;
    procedure Pack; virtual;
    procedure InsertExt(AItem : Pointer); virtual;
    procedure SetLimit(ALimit : integer); virtual;
    procedure AddExtObject; virtual;
    procedure AddExtItems; virtual;
    procedure DeleteExtItems;
    procedure FreeExtItems;
  end ;
  
```

371. Empty constructor. We can create an empty *MExtList*, which just assigns the array of items the **nil** value, the capacity is assigned zero, the logical size is assigned zero.

```

⟨ MExtList implementation 371 ⟩ ≡
constructor MExtList.Init(ALimit : integer);
begin MObject.Init;
Items ← nil;
Count ← 0; Limit ← 0;
SetLimit(ALimit); fExtCount ← 0;
end;
  
```

See also sections 372, 373, 375, 376, 377, 378, 379, 381, 382, 383, 384, 385, and 386.

This code is used in section 309.

372. Destructor for MExtList. The destructor for *MExtList* invokes *self.FreeExtItems* and then calls the inherited destructor from the superclass (§328).

```

⟨ MExtList implementation 371 ⟩ +≡
destructor MExtList.Done;
  begin FreeExtItems; inherited Done; end;

```

373. Inserting an item. If there are “undigested” extendible items, then we have a dilemma: where is the “end” of the list where we insert the new item? Do we shift all the “undigested” extendible items to the right by 1, and insert the argument at the end of the list of “digested” items? Do we need to track segments of digested and undigested items? This is clearly problematic, so we seek a simple solution: if there are any “undigested” extendible items, raise an error.

Otherwise, we possibly grow the extendible list, and we insert at the end the given pointer and increment the *Count* of items allocated. The new item is considered “digested”.

```

⟨ MExtList implementation 371 ⟩ +≡
procedure MExtList.Insert(aItem : Pointer);
  begin ⟨ Check all extendible items have been digested, otherwise raise error 374 ⟩;
  if Limit = Count then SetLimit(Limit + GrowLimit(Limit));
  Items↑[Count] ← aItem; { Append the item to the list }
  inc(Count);
  end;

```

374. Many methods for the *MExtList* class only make sense when all the extendible entries have been “digested” into the underlying array (i.e., when *fExtCount* = 0), otherwise we end up in a quagmire like the one outlined when discussing the *Insert* method and nothing makes sense anymore.

```

⟨ Check all extendible items have been digested, otherwise raise error 374 ⟩ ≡
  if fExtCount ≠ 0 then
    begin ListError(coIndexExtError, 0); exit;
  end

```

This code is used in sections 373, 375, 376, 377, 382, and 416.

375. Deleting all entries. When all the extendible entries have been “digested”, we call the parent’s *DeleteAll* method.

```

⟨ MExtList implementation 371 ⟩ +≡
procedure MExtList.DeleteAll;
  begin ⟨ Check all extendible items have been digested, otherwise raise error 374 ⟩;
  inherited DeleteAll; { (§338) }
  end;

```

376. Free all entries. Like deleting all the entries, we need to fully digest all the extendible entries before invoking the parent class’s *FreeAll* method. If there are extendible entries not fully digested, then we get indigestion (i.e., a list error).

```

⟨ MExtList implementation 371 ⟩ +≡
procedure MExtList.FreeAll;
  begin ⟨ Check all extendible items have been digested, otherwise raise error 374 ⟩;
  inherited FreeAll; { (§340) }
  end;

```

377. Packing. When packing an extendible list, we assert the extendible items have been digested fully. If not, raise an error. If fully digested, then invoke the parent class's *Pack* method.

```

⟨ MExtList implementation 371 ⟩ +≡
procedure MExtList.Pack;
  begin ⟨ Check all extendible items have been digested, otherwise raise error 374 ⟩;
  inherited Pack; { (§342) }
end;

```

378. Insert extendible items. We can add an extendible item by first growing the list (if necessary), then adding an item at index $N + k$. Then increment the number of extendible items $k \leftarrow k + 1$.

```

⟨ MExtList implementation 371 ⟩ +≡
procedure MExtList.InsertExt(AItem : Pointer);
  begin if Limit = Count + fExtCount then SetLimit(Limit + GrowLimit(Limit));
  Items↑[Count + fExtCount] ← AItem; inc(fExtCount);
end;

```

379. Ensure capacity of extendible list.

- (1) When the new limit is less than the logical size N and the extendible size k , we just set the capacity to $N + k$.
- (2) Else if the new limit is larger than *MaxCollectionSize*, then just use the maximum collection size as the capacity.
- (3) Else if the new limit is different than the existing capacity, then we have to check if the new limit is zero. When it is, just set the capacity to zero and the list of items to **nil**. Otherwise, allocate space for a new array, and move over the contents from the existing array (and then free the existing array). Update the capacity and pointer to the items.

```

⟨ MExtList implementation 371 ⟩ +≡
procedure MExtList.SetLimit(ALimit : integer);
  var UItems : PItemList;
  begin ⟨ Ensure Count + fExtCount ≤ ALimit ≤ MaxCollectionSize 380 ⟩;
  if ALimit ≠ Limit then
    begin if ALimit = 0 then UItems ← nil
    else begin GetMem(UItems, ALimit * SizeOf(Pointer));
      if ((Count + fExtCount) ≠ 0) ∧ (Items ≠ nil) then
        Move(Items↑, UItems↑, (Count + fExtCount) * SizeOf(Pointer));
      end;
    if Limit ≠ 0 then FreeMem(Items, Limit * SizeOf(Pointer));
    Items ← UItems; Limit ← ALimit;
    end;
  end;

```

380. ⟨ Ensure *Count* + *fExtCount* ≤ *ALimit* ≤ *MaxCollectionSize* 380 ⟩ ≡
if *ALimit* < *Count* + *fExtCount* **then** *ALimit* ← *Count* + *fExtCount*;
if *ALimit* > *MaxCollectionSize* **then** *ALimit* ← *MaxCollectionSize*

This code is used in section 379.

381. Mark the logical size. “Marking” an extendible list amounts to setting the procedure’s variable to the logical size of the extendible list.

[[This does not appear to be used anywhere.]]

$\langle MExtList \text{ implementation } 371 \rangle + \equiv$

```
procedure MExtList.Mark(var aIndex : integer);
begin aIndex  $\leftarrow$  Count;
end;
```

382. Hard delete “digested” items from an index to end. Freeing items starting at a given index requires the extendible items to be fully digested (if not, raise an error). Then simply free each object using the virtual destructor *MObject.Done*.

$\langle MExtList \text{ implementation } 371 \rangle + \equiv$

```
procedure MExtList.FreeItemsFrom(aIndex : integer);
var I: integer;
begin  $\langle$  Check all extendible items have been digested, otherwise raise error 374  $\rangle$ ;
for I  $\leftarrow$  Count - 1 downto aIndex do
  if Items $\uparrow$ [I]  $\neq$  nil then Dispose(PObject(Items $\uparrow$ [I]), Done);
  Count  $\leftarrow$  aIndex;
end;
```

383. Digesting one extendible item. We can instruct the extendible list to digest exactly one extendible item. This requires the number of extendible items to be positive $k > 0$. If not, raise an error. Otherwise increment the logical capacity $N \leftarrow N + 1$ and decrement the number of extendible items $k \leftarrow k - 1$.

$\langle MExtList \text{ implementation } 371 \rangle + \equiv$

```
procedure MExtList.AddExtObject;
begin if fExtCount  $\leq$  0 then
  begin ListError(coIndexExtError, 0); exit;
  end;
inc(Count); dec(fExtCount);
end;
```

384. Digest all extendible items. This simply updates capacity to be incremented by the number of extendible items. Then the number of extendible items is set to zero. No error is raised if there are no extendible items (unlike digesting one single extendible item).

$\langle MExtList \text{ implementation } 371 \rangle + \equiv$

```
procedure MExtList.AddExtItems;
begin Count  $\leftarrow$  Count + fExtCount; fExtCount  $\leftarrow$  0;
end;
```

385. Soft delete all extendible items. Deleting all extendible items simply sets the *number* of extendible items to zero. This is a “soft delete” which does not affect anything else on the heap.

$\langle MExtList \text{ implementation } 371 \rangle + \equiv$

```
procedure MExtList.DeleteExtItems;
begin fExtCount  $\leftarrow$  0;
end;
```

386. Hard delete all extendible items. Freeing all the extendible items will “hard delete” each extendible item, removing them from the heap.

$\langle MExtList$ implementation 371 $\rangle + \equiv$

procedure *MExtList.FreeExtItems*;

var *I*: integer;

begin for *I* \leftarrow 0 **to** *fExtCount* $-$ 1 **do**

if *Items* \uparrow [*Count* + *I*] \neq **nil** **then** *Dispose*(*PObject*(*Items* \uparrow [*Count* + *I*]), *Done*);

fExtCount \leftarrow 0;

end;

Section 10.6. SORTED LISTS

387. These are used in the equalizer and in the correlator, specifically for keeping a collection of identifiers.

A sorted list uses an array of indices (called *fIndex*). The array of indices are sorted according to a comparison of values.

Invariant: $Length(fIndex) = Length(Items)$

Invariant (sorted): for each $i = 0, \dots, Length(Items) - 2$, we have

$$Items \uparrow [fIndex \uparrow [i]] \leq Items \uparrow [fIndex \uparrow [i + 1]].$$

Also, we are taking the convention that $fCompare(x, y)$ returns -1 when $x < y$; returns 0 when $x = y$; returns $+1$ when $x > y$.

Fig. 3. UML class diagram for MSortedList class.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  { MSortedList Object }
  IndexListPtr = ↑MIndexList;
  MIndexList = array [0 .. MaxCollectionSize - 1] of integer;
  CompareProc = function (aItem1, aItem2 : Pointer): integer;
  MSortedList = object (MList)
    fIndex: IndexListPtr;
    fCompare: CompareProc;
    constructor Init(ALimit : integer);
    constructor InitSorted(aLimit : integer; aCompare : CompareProc);
    constructor MoveList(var aAnother : MList);
    constructor CopyList(const aAnother: MList);
    procedure AtInsert(aIndex : integer; aItem : Pointer); virtual;
    procedure Insert(aItem : Pointer); virtual;
    function IndexOf(aItem : Pointer): integer; virtual;
    procedure Sort(aCompare : CompareProc);
    procedure SetLimit(ALimit : integer); virtual;
    function Find(aKey : Pointer; var aIndex : integer): Boolean; virtual;
    function Search(aKey : Pointer; var aIndex : integer): Boolean; virtual;
    procedure Pack; virtual;
    procedure FreeItemsFrom(aIndex : integer); virtual;
  end ;
  
```

388. Constructors. There are four constructors:

- (1) *Init* simply creates an empty list with a given capacity.
- (2) *InitSorted* is like *Init*, but expects an ordering operator.
- (3) *MoveList* moves all the items from another list into the caller. This will also empty the other list.
- (4) *CopyList* is like *MoveList* but leaves the other list untouched.

$\langle \text{MSortedList implementation } 388 \rangle \equiv$
 {MSortedList object }

constructor *MSortedList.Init*(*aLimit* : integer);

begin *MObject.Init*; *Items* \leftarrow **nil**; *Count* \leftarrow 0; *Limit* \leftarrow 0; *fIndex* \leftarrow **nil**; *fCompare* \leftarrow **nil**;
SetLimit(*ALimit*);
end;

constructor *MSortedList.InitSorted*(*aLimit* : integer; *aCompare* : CompareProc);

begin *MObject.Init*; *Items* \leftarrow **nil**; *Count* \leftarrow 0; *Limit* \leftarrow 0; *fIndex* \leftarrow **nil**; *fCompare* \leftarrow *aCompare*;
SetLimit(*ALimit*);
end;

See also sections 389, 390, 391, 392, 394, 398, 400, 401, 404, 405, 407, and 408.

This code is used in section 309.

389. Move constructor. When we move items from an *MList* into the caller. A new array will be allocated for the indices. No sorting will occur. But the argument will be mutated to delete all the elements.

$\langle \text{MSortedList implementation } 388 \rangle + \equiv$

constructor *MSortedList.MoveList*(**var** *aAnother* : *MList*);

var *I*: integer;
begin *Items* \leftarrow *aAnother.Items*; *Count* \leftarrow *aAnother.Count*; *Limit* \leftarrow *aAnother.Limit*;
GetMem(*fIndex*, *Limit* * *SizeOf*(integer)); *fCompare* \leftarrow **nil**;
for *I* \leftarrow 0 **to** *pred*(*aAnother.Count*) **do** *fIndex* \uparrow [*I*] \leftarrow *I*;
 { Empty out the other list }
aAnother.DeleteAll; *aAnother.Limit* \leftarrow 0; *aAnother.Items* \leftarrow **nil**;
end;

390. The *CopyList* constructor is like the *MoveList* **except** that the other list is not modified, and a new array will be allocated for the *Items*.

$\langle \text{MSortedList implementation } 388 \rangle + \equiv$

constructor *MSortedList.CopyList*(**const** *aAnother*: *MList*);

var *i*: integer;
begin *MObject.Init*; *Items* \leftarrow **nil**; *Count* \leftarrow 0; *Limit* \leftarrow 0; *fIndex* \leftarrow **nil**; *fCompare* \leftarrow **nil**;
SetLimit(*aAnother.Limit*); *Count* \leftarrow *aAnother.Count*;
for *i* \leftarrow 0 **to** *Count* - 1 **do**
begin *Items* \uparrow [*i*] \leftarrow *PObject*(*aAnother.Items* \uparrow [*i*]) \uparrow .*MCopy*; *fIndex* \uparrow [*I*] \leftarrow *I*;
end;
end;

391. Insert element at an index. We can insert (potentially overwriting an existing entry) at a given index.

$\langle \text{MSortedList implementation 388} \rangle + \equiv$
 { used in CollectCluster not to repeat the search, should be used only when $@fCompare \neq \text{nil}$ }
procedure *MSortedList.AtInsert*(*aIndex* : integer; *aItem* : Pointer);
 begin if *Limit* = *Count* **then** *SetLimit*(*Limit* + *GrowLimit*(*Limit*)); { Ensure capacity }
 if *aIndex* \neq *Count* **then**
 Move(*fIndex* \uparrow [*aIndex*], *fIndex* \uparrow [*aIndex* + 1], (*Count* - *aIndex*) * *SizeOf*(integer));
 Items \uparrow [*Count*] \leftarrow *aItem*; *fIndex* \uparrow [*aIndex*] \leftarrow *Count*; *inc*(*Count*);
 end;

392. Inserting an item. Inserting an item into a sorted list boils down to two cases:

- (1) If there is an ordering operator, we check if the item is in the underlying array using *Find* (§401), which will mutate the *UIndex* to be where it should be located. When the item is missing, simply insert it at *UIndex*. When the item is present, then we do nothing.
- (2) If there is no ordering operator, then check if the item already is present in the sorted list. If so, then don't do anything. Otherwise, insert the item at the start of the list.

$\langle \text{MSortedList implementation 388} \rangle + \equiv$
procedure *MSortedList.Insert*(*aItem* : Pointer);
 var *UIndex*: integer;
 begin if $@fCompare = \text{nil}$ **then** $\langle \text{Insert item to the end of the caller 393} \rangle$;
 if $\neg \text{Find}(\text{aItem}, \text{UIndex})$ **then** *AtInsert*(*UIndex*, *aItem*);
 end;

393. $\langle \text{Insert item to the end of the caller 393} \rangle \equiv$
begin if *Limit* = *Count* **then** *SetLimit*(*Limit* + *GrowLimit*(*Limit*));
 Items \uparrow [*Count*] \leftarrow *aItem*; *fIndex* \uparrow [*Count*] \leftarrow *Count*; *inc*(*Count*); *exit*;
end

This code is used in section 392.

394. Resizing a sorted list. The invariant is that the list is sorted when it has an ordering operator (and so restricting to *aLimit* preserves the list being sorted), and it is a “set” when it does not have an ordering (and so restricting to *aLimit* preserves this property of being a finite set without duplicate entries).

$\langle \text{MSortedList implementation 388} \rangle + \equiv$
procedure *MSortedList.SetLimit*(*aLimit* : integer);
 var *UItems*: PItemList; *UIndex*: IndexListPtr;
 begin $\langle \text{Ensure } \text{Count} \leq \text{aLimit} \leq \text{MaxCollectionSize} \text{ for sorted lists 395} \rangle$;
 if *aLimit* \neq *Limit* **then**
 begin if *aLimit* = 0 **then**
 begin *UItems* \leftarrow nil; *UIndex* \leftarrow nil; **end**
 else $\langle \text{Allocate and copy items to new sorted list 396} \rangle$;
 $\langle \text{Free old arrays, if any 397} \rangle$;
 Items \leftarrow *UItems*; *fIndex* \leftarrow *UIndex*; *Limit* \leftarrow *aLimit*;
 end;
end;

395. $\langle \text{Ensure } \text{Count} \leq \text{aLimit} \leq \text{MaxCollectionSize} \text{ for sorted lists 395} \rangle \equiv$
if *aLimit* < *Count* **then** *aLimit* \leftarrow *Count*;
if *aLimit* > *MaxCollectionSize* **then** *aLimit* \leftarrow *MaxCollectionSize*

This code is used in section 394.

396. \langle Allocate and copy items to new sorted list 396 $\rangle \equiv$
begin *GetMem*(*lItems*, *aLimit* * *SizeOf*(*Pointer*)); *GetMem*(*lIndex*, *aLimit* * *SizeOf*(*integer*));
if *Count* \neq 0 **then**
 begin if *Items* \neq nil **then**
 begin *Move*(*Items* \uparrow , *lItems* \uparrow , *Count* * *SizeOf*(*Pointer*));
 Move(*fIndex* \uparrow , *lIndex* \uparrow , *Count* * *SizeOf*(*integer*));
 end;
 end;
end

This code is used in sections 394 and 419.

397. \langle Free old arrays, if any 397 $\rangle \equiv$
if *Limit* \neq 0 **then**
 begin *FreeMem*(*Items*, *Limit* * *SizeOf*(*Pointer*)); *FreeMem*(*fIndex*, *Limit* * *SizeOf*(*integer*));
 end

This code is used in sections 394 and 419.

398. Quick sort an array. We have a private helper function for quicksorting an *IndexListPtr* (§387). Initially $L \leftarrow 0$ and $R \leftarrow \text{length}(aList) - 1$. Specifically Mizar appears to use Hoare partitioning.

Algorithm S (*Quicksort*). This uses Hoare partition. We assume that $L \leq R$, and that *aCompare* is a total order (it's transitive and the law of trichotomy holds on all pairs of elements). Steps S1 through S4 are better known as the “partition” procedure.

- S0.** [Initialize] Set $I \leftarrow L$, $J \leftarrow R$, and the pivot index $P_{idx} \leftarrow (L + R) \text{ shr } 1$, and the pivot value $P \leftarrow aList \uparrow [aIndex \uparrow [(L + R) \text{ shr } 1]]$. Observe $I \leq P_{idx} \leq J$ at this point.
- S1.** [Move *I* right] While $aList[aIndex[I]] < P$, we increment $I \leftarrow I + 1$. This is guaranteed to terminate since $I \leq P_{idx}$, so eventually we will get to $aList[aIndex[I]] = P$. (Invariant: for all $0 \leq h < I$, we have $aList \uparrow [aIndex \uparrow [h]] < P$.)
- S2.** [Move *J* left] While $P < aList[J]$, we decrement $J \leftarrow J - 1$. This is guaranteed to terminate since $P_{idx} \leq J$, so eventually we will get to $aList[J] = P$. (Invariant: for all $J < k \leq \text{Count} - 1$, we have $P < aList \uparrow [aIndex[k]]$.)
- S3.** [Keep going?] If $I > J$, then we're done “partitioning” (so everything to the left of the pivot is not greater than the pivot value, and everything to the right of the pivot is not lesser than the pivot value), and we go to step S5; otherwise go to the next step.
- S4.** [Swap entries *I* and *J*] We swap the entries located at *I* and *J*, then set $I \leftarrow I + 1$, and $J \leftarrow J - 1$. If $I \leq J$, then return to step S1.
- S5.** [Recur on left half] If $L < J$, then recursively call quicksort on the left half of the index (entries between $L \dots J - 1$).
- S6.** [Sort the right half] If $I \geq R$, then terminate. Otherwise, set $L \leftarrow I$ and return to step S0. ■

For readability, we also introduce a **WEB** macro for swapping the indices.

define *steal_from*(#) $\equiv aIndex \uparrow [\#]$; $aIndex \uparrow [\#] \leftarrow T$;
define *swap_indices*(#) $\equiv T \leftarrow aIndex \uparrow [\#]$; $aIndex \uparrow [\#] \leftarrow \text{steal_from}$

$\langle \text{MSortedList implementation } 388 \rangle + \equiv$

procedure *ListQuickSort*(*aList* : *PItemList*; *aIndex* : *IndexListPtr*; *L*, *R* : *integer*;
 aCompare : *CompareProc*);
var *I*, *J*, *T* : *integer*; *P* : *Pointer*;
begin repeat $I \leftarrow L$; $J \leftarrow R$; $P \leftarrow aList \uparrow [aIndex \uparrow [(L + R) \text{ shr } 1]]$;
 repeat
 { $I \leq (L + R) \text{ shr } 1 \leq J$ }
 while $aCompare(aList \uparrow [aIndex \uparrow [I]], P) < 0$ **do** *inc*(*I*);
 { $P \leq aList \uparrow [aIndex \uparrow [I]]$ }
 while $aCompare(aList \uparrow [aIndex \uparrow [J]], P) > 0$ **do** *dec*(*J*);
 { $aList \uparrow [aIndex \uparrow [J]] \leq P$ }
 { $I \leq (L + R) \text{ shr } 1 \leq J$ }
 if $I \leq J$ **then**
 begin
 { $aList \uparrow [aIndex \uparrow [J]] < P < aList \uparrow [aIndex \uparrow [I]]$ }
 swap_indices(*I*)(*J*);
 { $aList \uparrow [aIndex \uparrow [I]] < P < aList \uparrow [aIndex \uparrow [J]]$ }
 { $I < J$ implies $\text{inc}(I) \leq \text{dec}(J)$ }
 { $I = J$ implies $\text{inc}(I) > \text{dec}(J)$ }
 inc(*I*); *dec*(*J*);
 end;
 until $I > J$;
 { $J \leq (L + R) \text{ shr } 2 \leq I$ and $J < I$ }
 if $L < J$ **then** *ListQuickSort*(*aList*, *aIndex*, *L*, *J*, *aCompare*); { quicksort left half }
 $L \leftarrow I$; { recursively quicksort the right half of the array }
 until $I \geq R$;

end;

399. Remarks.

- (1) It is unclear to me whether we must have $aCompare$ be a linear order, and not a total pre-order. The difference is: do we really need $a \leq b \wedge b \leq a \implies a = b$ (i.e., a total order) or not (i.e., a total pre-order)?
- (2) PRECONDITION: We need to prove the *compare* operators are total orders for quicksort to work as expected.
- (3) ASSERT: Upon arriving to step Q5, the entries in $L \dots J - 1$ are partitioned (i.e., less than the pivot value) as is the entries in $I \dots R$. In particular, the maximal element in $L \dots J - 1$ is located at $J - 1$ while the minimal element in $I \dots R$ is located at I .
- (4) It may be instructive to compare this quicksort to Algorithm Q in *The Art of Computer Programming*, third ed., volume 3, §5.2.2.
- (5) Robert Sedgewick's *Quicksort* (1980) is literally *the* book on the subject. An abbreviated reference may be found in Sedgewick's "The Analysis of Quicksort Programs" (*Acta Inform.* **7** (1977) 327–355, [eprint](#))
- (6) IMPROVEMENT: This can be improved when recursively sorting the left half of the arrays by first checking if $J - L \leq 9$ then use insertion sort otherwise recursively quicksort the left half. (Similarly, instead of iterating the outermost while-loop, we should test if $R - I \leq 9$ then invoking insertion on the subarray indexed by $I \dots R$.)
- (7) IMPROVEMENT: The pivot index P_{ind} is selected as $P_{ind} \leftarrow (L + R)/2$, which can lead to overflow. A safer way to compute this would be $P_{ind} \leftarrow L + ((R - L)/2)$.

According to the paper by Sedgewick we cited, when quicksorting a list of size less than M with a different sorting algorithm, the optimal choice of M (the cutoff for delegating to another sort algorithm) contributes to the runtime of quicksort,

$$f(M) = \frac{1}{6} \left(8M + 71 - 70H_{M+2} + \frac{270}{M+2} + \frac{54}{2M+3} - 36\frac{H_{M+1}}{M+2} \right).$$

We can use the approximation for Harmonic numbers

$$H_n = \ln(n) + \gamma + \frac{1}{2n} + O(n^{-2})$$

where $\gamma \approx 0.57721$ is Euler-Mascheroni constant. Using this replacement, we have

$$f'(M) \approx \frac{4}{3} + \frac{3}{(1+m)^2} - \frac{6}{1+m} + \frac{36\gamma - 253}{6(2+m)^2} - \frac{17}{3(2+m)} - \frac{18}{(3+2m)^2} + \frac{6\ln(1+m)}{(2+m)^2}.$$

We can numerically find the root for this to be $m_0 \approx 8.9888$ which gives a global minimum of $f(9) \approx -8.47671$.

This analysis is sketched out in Knuth's *The Art of Computer Programming*, volume III, but it may be worth sitting down and working this analysis out more fully.

400. Sorting a sorted list. We can update a sorted list to sort according to a new ordering operator, and also update the data structure to record this new ordering operator. This relies on *ListQuickSort* (§398) to do the actual sorting.

```

⟨ MSortedList implementation 388 ⟩ +≡
procedure MSortedList.Sort(aCompare : CompareProc);
  var I: integer;
  begin fCompare ← aCompare;
  for I ← 0 to Count − 1 do fIndex↑[I] ← I;
  if (Count > 0) then ListQuickSort(Items, fIndex, 0, Count − 1, aCompare);
  end;
```

401. Find item. Finding an item in a sorted list boils down to two cases: do we have *fCompare* populated or not? If so, then use a binary search. If not, then just iterate item-by-item testing if *aKey* is in the underlying array.

CAUTION: The “find” function returns the index for the *fIndex* field, **NOT** the index for the underlying array of values (inherited from the *MList* class).

```

⟨ MSortedList implementation 388 ⟩ +≡
function MSortedList.Find(aKey : Pointer; var aIndex : integer): Boolean;
  var L, H, I, C: integer;
  begin Find ← False;
  if @fCompare = nil then ⟨ Find needle in MSortedList by brute force 403 ⟩;
  ⟨ Find needle in MSortedList by binary search 402 ⟩
  end;

```

402. Binary search is a little clever. We have *L* be the lower bounds index, and *H* the upper bounds index. The midpoint is obtained by taking their sum $L + H$ and shifting to the right by 1 bit (which corresponds to dividing by 2, truncating the result).

We compare the item located at the midpoint to the given *aKey*, and store the result of this comparison in the variable *C*. If $C < 0$, then *aKey* is located to the right of the midpoint (so set $L \leftarrow I + 1$).

On the other hand, if $C \geq 0$, update $H \leftarrow I - 1$. When $C = 0$ (i.e., the midpoint *is equal to aKey*), then we set $L \leftarrow I + 1$ so we have $H < L$ to terminate the loop. We set the return value to *True* when $C = 0$, and we mutate the *aIndex* to the index where we found the needle in the haystack.

```

⟨ Find needle in MSortedList by binary search 402 ⟩ ≡
  L ← 0; H ← Count − 1;
  while L ≤ H do
    begin I ← (L + H) shr 1; C ← fCompare(Items↑[fIndex↑[I]], aKey);
    if C < 0 then L ← I + 1
    else begin H ← I − 1;
      if C = 0 then
        begin Find ← True; L ← I; end;
      end;
    end;
  aIndex ← L;

```

This code is used in section 401.

403. We can simply iterate through the underlying array, testing item-by-item if each entry is equal to the needle or not.

```

⟨ Find needle in MSortedList by brute force 403 ⟩ ≡
  begin aIndex ← Count;
  for I ← 0 to Count − 1 do
    if aKey = Items↑[I] then
      begin Find ← True; aIndex ← I; break end;
  exit;
end

```

This code is used in section 401.

404. Search. We recall that *Find* returns the index of the *fIndex* field matching the needle. Usually, we want to know the index of the value itself. This is what *Search* performs.

```

⟨ MSortedList implementation 388 ⟩ +≡
function MSortedList.Search(aKey : Pointer; var aIndex : integer): Boolean;
  var I: integer;
  begin aIndex ← Count; Search ← false;
  if Find(aKey, I) then
    begin Search ← true; aIndex ← fIndex↑[I];
    end;
  end;

```

405. Index of a needle. Given a “needle”, where in the haystack is it? Well, we require the ordering operator be non-nil for the sorted list — otherwise raise an error. Then using *Find* (§401), check if the entry is present. If it is, then return the index for the underlying array of values.

If the needle is not in the haystack, return -1 . [The assertion that *fCompare* is present turns out to be unnecessary: the rest of the function works.]

```

⟨ MSortedList implementation 388 ⟩ +≡
function MSortedList.IndexOf(aItem : Pointer): integer;
  var I: integer;
  begin ⟨ Assert fCompare is present 406 ⟩;
  IndexOf ←  $-1$ ;
  if Find(aItem, I) then
    begin { if I < fCount then }
    IndexOf ← fIndex↑[I];
    end;
  end;

```

```

406. ⟨ Assert fCompare is present 406 ⟩ ≡
  if @fCompare = nil then
    begin ListError(coSortedListError, 0); exit;
    end

```

This code is used in sections 405 and 426.

407. Packing a sorted list. Use the superclass’s *Pack* method. Then, when there is an ordering operator present, sort the list.

```

⟨ MSortedList implementation 388 ⟩ +≡
procedure MSortedList.Pack;
  var lCount: integer;
  begin lCount ← Count; inherited Pack; { (§342) }
  if (@fCompare ≠ nil) ∧ (lCount > Count) then Sort(fCompare);
  end;

```

408. Free items starting at an index. When we want to remove all items starting at index a , we simply iterate through the array of indices starting at entry $i = a$ and delete the value associated with $Items[i]$ when it is non-**nil**.

This will also keep the indices for the non-deleted entries.

$\langle MSortedList$ implementation 388 $\rangle + \equiv$
procedure *MSortedList.FreeItemsFrom*(*aIndex* : integer);
 var *I, k*: integer;
 begin if *aIndex* = *Count* **then** *exit*;
 { Delete entries from the array of values }
 for *I* \leftarrow *aIndex* **to** *Count* - 1 **do**
 if *Items* \uparrow [*I*] \neq **nil** **then** *Dispose*(*PObject*(*Items* \uparrow [*I*]), *Done*);
 { Update the array of indices }
 k \leftarrow 0;
 for *I* \leftarrow 0 **to** *Count* - 1 **do**
 begin if *fIndex* \uparrow [*I*] < *aIndex* **then**
 begin *fIndex* \uparrow [*k*] \leftarrow *fIndex* \uparrow [*I*]; *inc*(*k*); **end**;
 end;
 if *k* \neq *aIndex* **then** *ListError*(*coSortedListError*, 0);
 Count \leftarrow *aIndex*;
end;

Section 10.7. SORTED EXTENDIBLE LISTS

409. We want to handle a sorted (§387) version of extendible lists (§370) — an *MSortedExtList*. It's used in the correlator for functorial registrations and inferred definition constants.

Like *MSortedList*, we add a field *fIndex* for the indices of the entries. This will track the *digested* items, not the extendible items.

An important invariant: the ordering operator (*fCompare*) must be non-**nil**.

Fig. 4. UML class diagram for *MSortedExtList* class.

```

⟨Public interface for mobjects.pas 310⟩ +≡
MSortedExtList = object (MExtList)
  fIndex: IndexListPtr;
  fCompare: CompareProc;
  constructor Init(ALimit : integer);
  constructor InitSorted(aLimit : integer; aCompare : CompareProc);
  destructor Done; virtual;
  function Find(aKey : Pointer; var aIndex : integer): Boolean; virtual;
  function FindRight(aKey : Pointer; var aIndex : integer): Boolean; virtual;
  function FindInterval(aKey : Pointer; var aLeft, aRight : integer): Boolean; virtual;
  function AtIndex(aIndex : integer): Pointer; virtual;
  procedure Insert(aItem : Pointer); virtual;
  procedure Pack; virtual;
  procedure InsertExt(AItem : Pointer); virtual;
  procedure SetLimit(ALimit : integer); virtual;
  procedure FreeItemsFrom(aIndex : integer); virtual;
  procedure AddExtObject; virtual;
  procedure AddExtItems; virtual;
end ;
  
```

410. Constructors. The *Init* constructor should not be used, and should raise an error if anyone tries to use it.

Instead, the *InitSorted* should be used to construct a new [empty] sorted extendible list with a given ordering operator.

```

⟨MSortedExtList implementation 410⟩ ≡
{ MSortedExtList always with possible duplicate keys, always sorted }
constructor MSortedExtList.Init(ALimit : integer);
  begin ListError(coIndexExtError, 0); end;
constructor MSortedExtList.InitSorted(aLimit : integer; aCompare : CompareProc);
  begin inherited Init(aLimit); fCompare ← aCompare;
  end;
  
```

See also sections 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, and 422.

This code is used in section 309.

411. Destructor The destructor for sorted extendible lists is just the inherited destructor from extendible lists.

```

⟨ MSortedExtList implementation 410 ⟩ +≡
destructor MSortedExtList.Done;
  begin inherited Done; end;

```

412. Finding a needle in the haystack. We require *fCompare* to be non-**nil** and enforce that invariant by raising an error when it is **nil**.

Then we just use bisection search to find the needle in the haystack. Once found, we mutate *aIndex* to the index *L* of the *fIndex* array which indexes the needle.

The claim is that this will find the left-most index for the needle. To see this claim, work out the result of searching for “*d*” in the list [*a, b, c, d, d, d, e, f, g*] where indices range from 0 to 9, using the usual ordering $a < b < c < d < e < f < g$.

It is also instructive to work out the case searching for *c* in the list [*a, b, c, c, d*] indexed from 0 to 4. Again, the ordering is $a < b < c < d$. The first iteration will set $I \leftarrow 2$, which points to the first entry with a *c*. (I have written a unit test for this case, it is true: *Find* will return *true* and mutate $aIndex \leftarrow 2$.)

Ensures: if the result is *true*, then *aIndex* will be the left-most index for *aKey*.

```

⟨ MSortedExtList implementation 410 ⟩ +≡
{ find the left-most if duplicates }
function MSortedExtList.Find(aKey : Pointer; var aIndex : integer): Boolean;
  var L, { low index }
      H, { high index }
      I, { index of candidate entry }
      C: integer; { result comparing entry I to aKey }
  begin if  $\neg \text{Assigned}(fCompare)$  then ListError(coIndexExtError, 0);
  Find  $\leftarrow$  False; L  $\leftarrow$  0; H  $\leftarrow$  Count - 1;
  while  $L \leq H$  do
    begin  $I \leftarrow (L + H) \text{ shr } 1$ ;  $C \leftarrow fCompare(Items \uparrow [fIndex \uparrow [I]], aKey)$ ;
    if  $C < 0$  then  $L \leftarrow I + 1$  { needle is in right half of haystack }
    else begin  $H \leftarrow I - 1$ ;
      if  $C = 0$  then Find  $\leftarrow$  True;
    end;
  end;
  aIndex  $\leftarrow$  L;
end;

```

413. Find the rightmost index for a needle in the haystack. Since the underlying array is sorted, we check to see if the needle is in the haystack. If it is, we keep incrementing *aIndex* until it is no longer indexing the needle.

So upon return, if it returns *True*, then the *aIndex* parameter is mutated to equal the rightmost index for the needle's appearance in the haystack.

Ensures: if the result is *true*, then the entry at *aIndex* - 1 will be equal to the *aKey* but the entry at *aIndex* will not be equal to *aKey*.

```

define scan_right(#)  $\equiv$  while (# < Count)  $\wedge$  (0 = fCompare(Items $\uparrow$ [fIndex $\uparrow$ [#]], aKey)) do inc(#)
 $\langle$  MSortedExtList implementation 410  $\rangle$   $\equiv$ 
{ find the left-most with higher aKey, this is where we can insert }
function MSortedExtList.FindRight(aKey : Pointer; var aIndex : integer): Boolean;
begin if Find(aKey, aIndex) then
  begin scan_right(aIndex); FindRight  $\leftarrow$  true;
  end
else FindRight  $\leftarrow$  false;
end;

```

414. Finding all instances of a needle. Since we allow duplicate values in a sorted extendible list, we will sometimes wish to know the “interval” of entries equal to a needle. This will mutate *aLeft* and *aRight* to point to the beginning and end of the interval. When present, the result will have *aLeft* \leq *aRight* and for any *i* such that *aLeft* $\leq i \leq$ *aRight* we will have *compare*(*Items* \uparrow [*fIndex* \uparrow [*i*]], *aKey*) = 0.

When the needle is not in the haystack, the function will mutate the variables to ensure *aRight* < *aLeft* to stress the point.

```

 $\langle$  MSortedExtList implementation 410  $\rangle$   $\equiv$ 
{ find the interval of equal guys }
function MSortedExtList.FindInterval(aKey : Pointer; var aLeft, aRight : integer): Boolean;
begin if Find(aKey, aLeft) then
  begin aRight  $\leftarrow$  aLeft + 1; scan_right(aRight); dec(aRight); FindInterval  $\leftarrow$  true;
  end
else begin aRight  $\leftarrow$  aLeft - 1; FindInterval  $\leftarrow$  false;
  end;
end;

```

415. Get value at index. We check if the index *i* is within bounds of the sorted extendible list. If not, then we raise an error.

Otherwise, the default course of action, we simply lookup the entry *fIndex*[*i*] and then lookup the entry in the array of values located with that index.

```

 $\langle$  MSortedExtList implementation 410  $\rangle$   $\equiv$ 
function MSortedExtList.AtIndex(aIndex : integer): Pointer;
begin if (aIndex < 0)  $\vee$  (aIndex  $\geq$  Count) then ListError(coIndexExtError, 0);
  AtIndex  $\leftarrow$  Items $\uparrow$ [fIndex $\uparrow$ [aIndex]];
end;

```

416. Inserting items. We can only insert an item into an extendible list when it has fully digested all its extendible items. This requirement carries over to sorted extendible lists.

When there are no extendible items, we delegate the work to *InsertExt*.

```

 $\langle$  MSortedExtList implementation 410  $\rangle$   $\equiv$ 
procedure MSortedExtList.Insert(aItem : Pointer);
begin  $\langle$  Check all extendible items have been digested, otherwise raise error 374  $\rangle$ ;
  InsertExt(aItem); AddExtObject;
end;

```

417. Packing a sorted extendible list is unsupported, so just raise an error if anyone tries to use it.

$\langle \text{MSortedExtList implementation 410} \rangle + \equiv$

```
procedure MSortedExtList.Pack;
  begin ListError(coIndexExtError, 0);
  end;
```

418. Adding an extendible item. We ensure there is sufficient capacity in the underlying array of items, then add *AItem* at the position located by the logical size of the array of items. We also increment the number of extendible items.

$\langle \text{MSortedExtList implementation 410} \rangle + \equiv$

```
procedure MSortedExtList.InsertExt(AItem : Pointer);
  begin if Limit = Count + fExtCount then SetLimit(Limit + GrowLimit(Limit));
  Items↑[Count + fExtCount] ← AItem; inc(fExtCount);
  end;
```

419. Ensure capacity. We can ensure the capacity of a sorted extendible list to be at least as large as *ALimit*.

When *ALimit* is smaller than the current capacity of the sorted extendible list, we allocate new arrays and copy over the old data. More importantly: we keep the last *fExtCount* items as (“undigested”) extendible items.

$\langle \text{MSortedExtList implementation 410} \rangle + \equiv$

```
procedure MSortedExtList.SetLimit(ALimit : integer);
  var lItems: PItemList; lIndex: IndexListPtr;
  begin Count ← Count + fExtCount;  $\langle \text{Ensure } \textit{Count} \leq \textit{ALimit} \leq \textit{MaxCollectionSize} \text{ 344} \rangle$ ;
  if aLimit ≠ Limit then
    begin if aLimit = 0 then
      begin lItems ← nil; lIndex ← nil;
      end
    else  $\langle \text{Allocate and copy items to new sorted list 396} \rangle$ ;
     $\langle \text{Free old arrays, if any 397} \rangle$ ;
    Items ← lItems; fIndex ← lIndex; Limit ← aLimit; { Update the caller to use new arrays }
    end;
  Count ← Count − fExtCount;
  end;
```

420. Freeing items starting at an index. We have two exceptional situations:

- (1) The $fExtCount$ must be zero, and if it is nonzero, then an error is raised; and
- (2) If the index given is equal to the logical size of the sorted extendible list, then we terminate early (since there is nothing to do).

$\langle MSortedExtList$ implementation 410 $\rangle + \equiv$

```

procedure MSortedExtList.FreeItemsFrom(aIndex : integer);
  var I, k: integer;
  begin if  $fExtCount \neq 0$  then ListError(coIndexExtError, 0);
  if  $aIndex = Count$  then exit;
  { Free items indexed by  $I \geq aIndex$  }
  for  $I \leftarrow aIndex$  to  $Count - 1$  do
    if  $Items \uparrow [I] \neq \text{nil}$  then Dispose(PObject( $Items \uparrow [I]$ ), Done);
  { Sort  $fIndex$  for entries less than  $aIndex$  }
   $k \leftarrow 0$ ;
  for  $I \leftarrow 0$  to  $Count - 1$  do
    begin if  $fIndex \uparrow [I] < aIndex$  then
      begin  $fIndex \uparrow [k] \leftarrow fIndex \uparrow [I]$ ; inc( $k$ );
      end;
    end;
  if  $k \neq aIndex$  then ListError(coSortedListError, 0);
   $Count \leftarrow aIndex$ ;
end;

```

421. Digest an extendible object. When there are extendible objects left to digest among the values (i.e., when $fExtCount > 0$), When $fExtCount \leq 0$, then raise an error (there's nothing left to digest).

The first extendible item left to be digested is located at $Count$ in the array of items. Then we find the right most index for the same extendible item. We digest all of them at once, shifting the $fIndex$ as needed.

Note that the need to shift $fIndex$ down by 1 is needed to keep the array of items sorted.

$\langle MSortedExtList$ implementation 410 $\rangle + \equiv$

```

procedure MSortedExtList.AddExtObject;
  var UIndex: integer;
  begin if  $fExtCount \leq 0$  then ListError(coIndexExtError, 0);
  FindRight( $Items \uparrow [Count]$ , UIndex);
  if  $UIndex \neq Count$  then { shift  $fIndex$  to right by 1 }
    Move( $fIndex \uparrow [UIndex]$ ,  $fIndex \uparrow [UIndex + 1]$ ,  $(Count - UIndex) * SizeOf(integer)$ );
   $fIndex \uparrow [UIndex] \leftarrow Count$ ; { extendible item's index }
  inc( $Count$ ); dec( $fExtCount$ );
end;

```

422. Digest all extendible items. We can simply iterate through all the extendible items, digesting them one-by-one.

$\langle MSortedExtList$ implementation 410 $\rangle + \equiv$

```

procedure MSortedExtList.AddExtItems;
  begin while  $fExtCount > 0$  do AddExtObject;
end;

```

Section 10.8. SORTED LIST OF STRINGS

423. This is used in the kernel to track directives, as well as `makenv` and `accdict` needs it.

Fig. 5. UML class diagram for `MSortedStrList` class.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  MSortedStrList = object (MSortedList)
    constructor Init(ALimit : integer);
    function IndexOfStr(const aStr: string): integer; virtual;
    function ObjectOf(const aStr: string): PObject; virtual;
  end ;

```

424. Pointer comparison. For strings, it is faster to use pointer comparison than lexicographic ordering. Although pointer comparison is a total linear order, it may not produce intuitive comparisons.

```

⟨MSortedStrList implementation 424⟩ ≡
  { MSortedStrList }
function CompareStringPtr(aKey1, aKey2 : Pointer): integer;
begin if PStr(aKey1)↑.fStr < PStr(aKey2)↑.fStr then CompareStringPtr ← -1
else if PStr(aKey1)↑.fStr = PStr(aKey2)↑.fStr then CompareStringPtr ← 0
else CompareStringPtr ← 1;
end;

```

This code is used in section 309.

425. Constructor. We just defer to the `InitSorted` constructor for sorted lists (§388).

As an invariant, the `fCompare` ordering operator is *always* assumed to be set to the `CompareStringPtr`. There is no other way to construct a sorted string list besides this constructor, which enforces this invariant.

```

constructor MSortedStrList.Init(ALimit : integer);
begin InitSorted(ALimit, CompareStringPtr);
end;

```

426. We can locate a string by *Find*-ing its entry in the `fIndex` array.

```

function MSortedStrList.IndexOfStr(const aStr: string): integer;
var I: integer; lStringObj: MStrObj;
begin IndexOfStr ← -1; ⟨Assert fCompare is present 406⟩; {Invariant violation}
  lStringObj.Init(aStr);
  if Find(@lStringObj, I) then
    begin if I < Count then IndexOfStr ← fIndex↑[I];
    end;
  end;
end;

```

427. We also can return the pointer to the object, if it is present in the sorted string list.

```

function MSortedStrList.ObjectOf(const aStr: string): PObject;
var I: integer;
begin ObjectOf ← nil; I ← IndexOfStr(aStr);
  if I ≥ 0 then ObjectOf ← Items↑[I];
end;

```

Section 10.9. SORTED COLLECTIONS

428. With *MSortedList*, it was cheaper to move indices around than moving object around. But the goal was to have an array which we could sort “fast enough”.

What we want to consider now is a “finite set”-like collection. The usual way to implement such a data structure is to use a sorted list, and to avoid inserting duplicate entries.

Fig. 6. UML class diagram for MSortedCollection class.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  { MSortedCollection object }
  PSortedCollection = ↑MSortedCollection;
  MSortedCollection = object (MCollection)
    Duplicates: Boolean;
    fCompare: CompareProc;
    constructor Init(ALimit, ADelta : integer);
    constructor InitSorted(ALimit, ADelta : integer; aCompare : CompareProc);
    function Compare(Key1, Key2 : Pointer): integer; virtual;
    function IndexOf(aItem : Pointer): integer; virtual;
    procedure Insert(aItem : Pointer); virtual;
    procedure InsertD(Item : Pointer); virtual;
    function KeyOf(Item : Pointer): Pointer; virtual;
    function Search(Key : Pointer; var Index : integer): Boolean; virtual;
  end ;

```

429. Constructors. We can construct a sorted collection without an ordering operator, and we can construct one with an ordering operator.

```

⟨MSortedCollection implementation 429⟩ ≡
  { MSortedCollection }
  constructor MSortedCollection.Init(aLimit, aDelta : integer);
    begin inherited Init(ALimit, ADelta); Duplicates ← False; fCompare ← nil;
  end;
  constructor MSortedCollection.InitSorted(aLimit, aDelta : integer; aCompare : CompareProc);
    begin inherited Init(ALimit, ADelta); Duplicates ← False; fCompare ← aCompare;
  end;

```

This code is used in section 309.

430. Comparing entries. This will invoke *Abstract1* (§308) when there is no ordering operator, which itself raises an error 211.

Otherwise, this just invokes *fCompare* on the two entries.

```

function MSortedCollection.Compare(Key1, Key2 : Pointer): integer;
  begin if @fCompare = nil then Abstract1;
    Compare ← fCompare(Key1, Key2);
  end;

```

431. We treat the item itself as the key, so return the item. That is to say, this is the identity function. It does not mutate the caller.

```
function MSortedCollection.KeyOf(Item : Pointer): Pointer;
  begin KeyOf  $\leftarrow$  Item;
  end;
```

432. Binary search. This is binary search through a sorted collection. This will mutate the *Index* argument to point to where the *Key* is located if it is present (or where it should be located if it is absent). If there are duplicates, this will assign *Index* the left-most index.

When the *Key* is present in the collection, this function will return *true*. Otherwise, it will return *false*.

It may be instructive for the reader to compare this to *MSortedExtList*'s *Find* method (§412).

[[I think if there are no duplicates, then “**begin** ; *Index* \leftarrow *L*; *exit*; **end**;” should be the body of the **if** statement. Nothing changes, but it avoids needless iterations.]]

```
function MSortedCollection.Search(Key : Pointer; var Index : integer): Boolean;
  var L, H, I, C: integer;
  begin Search  $\leftarrow$  False; L  $\leftarrow$  0; H  $\leftarrow$  Count - 1;
  while L  $\leq$  H do
    begin I  $\leftarrow$  (L + H) shr 1; C  $\leftarrow$  Compare(KeyOf(Items $\uparrow$ [I]), Key);
    if C < 0 then L  $\leftarrow$  I + 1
    else begin H  $\leftarrow$  I - 1;
      if C = 0 then
        begin Search  $\leftarrow$  True;
        if  $\neg$ Duplicates then L  $\leftarrow$  I;
        end;
      end;
    end;
  Index  $\leftarrow$  L;
  end;
```

433. Find the right-most index for an item in the collection. Searching (§432) for the *KeyOf* (§431). I have just unit tested this, the branch incrementing *I* is buggy. It should be something like:

$$\text{while } (I + 1 < \text{Count}) \wedge (aItem = \text{Items}\uparrow[I + 1]) \text{ do } inc(I); \text{ IndexOf} \leftarrow I;$$

This will scan to the right until we get to the end of the collection, or the next item is no longer the same thing the user is searching for.

```
function MSortedCollection.IndexOf(aItem : Pointer): integer;
  var I: integer;
  begin IndexOf  $\leftarrow$  -1;
  if Search(KeyOf(aItem), I) then
    begin if Duplicates then
      while (I < Count)  $\wedge$  (aItem  $\neq$  Items $\uparrow$ [I]) do inc(I);
      if I < Count then IndexOf  $\leftarrow$  I;
      end;
    end;
  end;
```

434. Insert the item when it is not in the collection (or if duplicates are allowed). Otherwise do not mutate the caller.

```
procedure MSortedCollection.Insert(aItem : Pointer);
  var I: integer;
  begin if  $\neg$ Search(KeyOf(aItem), I)  $\vee$  Duplicates then AtInsert(I, aItem);
  end;
```

435. Insert an item if it's not in the collection (or if there are duplicates allowed in the collection). Otherwise, delete the item and do not mutate the caller.

```
procedure MSortedCollection.InsertD(Item : Pointer);
  var I: integer;
  begin if  $\neg$ Search(KeyOf(Item), I)  $\vee$  Duplicates then AtInsert(I, Item)
  else Dispose(PObject(Item), Done);
  end;
```

436. Perform the lexicographic ordering of (x_1, y_1) against (x_2, y_2) .

```
function CompareIntPairs(X1, Y1, X2, Y2 : Longint): integer;
  var lRes: integer;
  begin lRes  $\leftarrow$  CompareInt(X1, X2);
  if lRes = 0 then lRes  $\leftarrow$  CompareInt(Y1, Y2);
  CompareIntPairs  $\leftarrow$  lRes;
  end;
```

Section 10.10. STRING COLLECTION

437. The `librenv.pas` module uses both the *MStringCollection* and *StringColl* data structures.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  { MStringCollection object }
  PStringCollection = ↑MStringCollection;
  MStringCollection = object (MSortedCollection)
    function Compare(Key1, Key2 : Pointer): integer; virtual;
    procedure FreeItem(Item : Pointer); virtual;
  end ;
  { UnsortedStringCollection }
  PUnsortedStringCollection = ↑StringColl;
  StringColl = object (MCollection)
    procedure FreeItem(Item : pointer); virtual;
  end ;

```

438. String ordering operator. We have the usual lexicograph ordering as an operator ordering.

```

⟨String collection implementation 438⟩ ≡
  { MStringCollection }
function CompareStr(aStr1, aStr2 : string): integer;
  begin if aStr1 < aStr2 then CompareStr ← -1
  else if aStr1 = aStr2 then CompareStr ← 0
  else CompareStr ← 1;
  end;

```

This code is used in section 309.

439. We then have a convenience function to handle pointer dereferencing.

```

function MStringCollection.Compare(Key1, Key2 : Pointer): integer;
  begin Compare ← CompareStr(PString(Key1)↑, PString(Key2)↑);
  end;

```

440. Freeing items. We can free an item by simply freeing the string. This is the same for unsorted string collections, too.

```

procedure MStringCollection.FreeItem(Item : Pointer);
  begin DisposeStr(Item);
  end;
{ UnsortedStringCollection }
procedure StringColl.FreeItem(Item : pointer);
  begin DisposeStr(Item);
  end;

```

Section 10.11. INT COLLECTIONS

441. The *TIntItem* is needed for the unifier and equalizer.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  { MIntCollection object }
  IntPair = record X, Y: integer;
  end;
  IntPairItemPtr = ↑IntPairItem;
  IntPairItem = object (MObject)
    fKey: IntPair;
    constructor Init(X, Y : integer);
  end ;
  IntPtr = ↑integer;
  PIntItem = ↑TIntItem;
  TIntItem = object (MObject)
    IntKey: integer;
    constructor Init(fInt : integer);
  end ;
  PIntKeyCollection = ↑TIntKeyCollection;
  TIntKeyCollection = object (MSortedCollection)
    function KeyOf(Item : pointer): pointer; virtual;
    function Compare(Key1, Key2 : pointer): integer; virtual;
  end ;
  IntPairKeyCollectionPtr = ↑IntPairKeyCollection;
  IntPairKeyCollection = object (MSortedCollection)
    function Compare(Key1, Key2 : pointer): integer; virtual;
    function ObjectOf(X, Y : integer): IntPairItemPtr; virtual;
    function FirstThat(X : integer): IntPairItemPtr; virtual;
  end ;

```

442. TIntItem constructor. This just copies the given integer over to the newly allocated *TIntItem* object.

```

⟨MIntCollection implementation 442⟩ ≡
  { MIntCollection }
  constructor TIntItem.Init(fInt : integer);
  begin IntKey ← fInt;
  end;

```

This code is used in section 309.

443. We use *TIntItems* as keys in a *TIntKeyCollection*.

```

function TIntKeyCollection.KeyOf(Item : pointer): pointer;
begin KeyOf ← addr(PIntItem(Item)↑.IntKey);
end;

```

444. Comparing items just looks at the integers referred by the pointers.

```
function TIntKeyCollection.Compare(Key1, Key2 : pointer): integer;
  begin Compare  $\leftarrow$  1;
  if IntPtr(Key1) $\uparrow$  < IntPtr(Key2) $\uparrow$  then
    begin Compare  $\leftarrow$  -1; exit
    end;
  if IntPtr(Key1) $\uparrow$  = IntPtr(Key2) $\uparrow$  then Compare  $\leftarrow$  0;
  end;
```

445. Constructor for pairs of integers.

```
constructor IntPairItem.Init(X, Y : integer);
  begin fKey.X  $\leftarrow$  X; fKey.Y  $\leftarrow$  Y;
  end;
```

446. Comparing two keys in a collection indexed by *IntPairs* is done “in the obvious way”.

```
function IntPairKeyCollection.Compare(Key1, Key2 : pointer): integer;
  begin Compare  $\leftarrow$  CompareIntPairs(IntPairItemPtr(Key1) $\uparrow$ .fKey.X, IntPairItemPtr(Key1) $\uparrow$ .fKey.Y,
    IntPairItemPtr(Key2) $\uparrow$ .fKey.X, IntPairItemPtr(Key2) $\uparrow$ .fKey.Y);
  end;
```

447. We can lookup the value associated to the key (*X*, *Y*) leveraging the *MSortedCollection.Search* function.

```
function IntPairKeyCollection.ObjectOf(X, Y : integer): IntPairItemPtr;
  var lPairItem: IntPairItem; I: integer;
  begin ObjectOf  $\leftarrow$  nil; lPairItem.Init(X, Y);
  if Search(addr(lPairItem), I) then ObjectOf  $\leftarrow$  Items $\uparrow$ [I];
  end;
```

448. This is used in *justhan.pas* and *mizprep.pas*.

```
function IntPairKeyCollection.FirstThat(X : integer): IntPairItemPtr;
  var I: integer;
  begin FirstThat  $\leftarrow$  nil;
  for i  $\leftarrow$  0 to Count - 1 do
    if IntPairItemPtr(Items $\uparrow$ [I]) $\uparrow$ .fKey.X = X then
      begin FirstThat  $\leftarrow$  Items $\uparrow$ [I]; exit
      end;
  end;
```

Section 10.12. STACKED LIST OF OBJECTS

449. “Stacked” lists are really linked lists. This is an abstract class, so the methods are not implemented (and trying to use them will raise an error).

```

⟨ Public interface for mobjects.pas 310 ⟩ +≡
  { Stacked Object (List of objects) }
  StackedPtr = ↑StackedObj;
  StackedObj = object (MObject)
    Previous: StackedPtr;
    constructor Init;
    destructor Done; virtual;
  end ;

```

450. The constructors and destructors are not implemented, so if you try to use them, just raise an error.

```

⟨ Stacked object implementation 450 ⟩ ≡
  { Stacked Object (List of objects) }
constructor StackedObj.Init;
  begin Abstract1;
  end;
destructor StackedObj.Done;
  begin Abstract1;
  end;

```

This code is used in section 309.

Section 10.13. STRING LIST

451. We will want to use a dictionary whose keys are strings, and values are pointers to *MObjects*. The *MStringList* is such a dictionary. It's little more than an array of *MStringItem* entries, sorted according to key.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  { MStringList object }
  PStringItem = ↑MStringItem;
  MStringItem = record fString: PString; { key }
                fObject: PObject; { value }
  end;

```

```

452. ⟨Public interface for mobjects.pas 310⟩ +≡
  MDuplicates = (dupIgnore, dupAccept, dupError);
  PStringItemList = ↑MStringItemList;
  MStringItemList = array [0 .. MaxListSize] of MStringItem;
  PStringList = ↑MStringList;
  MStringList = object (MObject)
    fList: PStringItemList;
    fCount: integer; { logical size }
    fCapacity: integer; { capacity of array }
    fSorted: Boolean;
    fDuplicate: MDuplicates; { how to handle duplicates }
    constructor Init(aCapacity: integer);
    constructor MoveStringList(var aAnother: MStringList);
    ⟨Declare internal methods for StringList 453⟩
    procedure SetSorted(aValue: Boolean);
    procedure Sort; virtual;
    function GetString(aIndex: integer): string; virtual;
    function GetObject(aIndex: integer): PObject; virtual;
    procedure PutString(aIndex: integer; const aStr: string); virtual;
    procedure PutObject(aIndex: integer; aObject: PObject); virtual;
    procedure SetCapacity(aCapacity: integer); virtual;
    destructor Done; virtual;
    function AddString(const aStr: string): integer; virtual;
    function AddObject(const aStr: string; aObject: PObject): integer; virtual;
    procedure AddStrings(var aStrings: MStringList); virtual;
    procedure Clear; virtual;
    procedure Delete(aIndex: integer); virtual;
    procedure Exchange(Index1, Index2: integer); virtual;
    procedure MoveObject(CurIndex, NewIndex: integer); virtual;
    function Find ( const aStr: string ; var aIndex: integer ) : Boolean; virtual;
    function IndexOf(const aStr: string): integer; virtual;
    function ObjectOf(const aStr: string): PObject; virtual;
    function IndexOfObject(aObject: PObject): integer;
    procedure Insert(aIndex: integer ; const aStr: string); virtual;
    procedure InsertObject(aIndex: integer ; const aStr: string; aObject: PObject);
  end ;

```

453. [[These methods should be declared ‘private’, to enforce the implicit constraint that these methods should not be used directly.]]

```

⟨ Declare internal methods for StringList 453 ⟩ ≡
  { – Internal methods- do not use them directly – }
procedure StringListError(Code, Info : integer); virtual;
procedure Grow;
procedure QuickSort(L, R : integer);
procedure ExchangeItems(Index1, Index2 : integer);
procedure InsertItem(aIndex : integer ; const aStr : string);

```

This code is used in section 452.

454. Constructors. We can construct an empty string collection using *Init*. We can also move the contents of *aAnother* string collection into the caller using *MoveStringList*.

```

⟨ String list implementation 454 ⟩ ≡
  { ————— MStringList ————— }
constructor MStringList.Init(aCapacity : integer); { empty dictionary constructor }
  begin MObject.Init; fList ← nil; fCount ← 0; fCapacity ← 0; fSorted ← false;
    fDuplicate ← dupError; SetCapacity(aCapacity);
  end;
constructor MStringList.MoveStringList(var aAnother : MStringList);
  begin MObject.Init; fCount ← aAnother.fCount; fCapacity ← aAnother.fCapacity;
    fSorted ← aAnother.fSorted; fList ← aAnother.fList; fDuplicate ← aAnother.fDuplicate;
    { Empty out the other list }
    aAnother.fCount ← 0; aAnother.fCapacity ← 0; aAnother.fList ← nil;
  end;

```

See also sections 457 and 460.

This code is used in section 309.

455. Destructor. Since a *MStringItem* is a pointer to a string and a pointer to an *MObject*, freeing an *MStringItem* should free both of these (when they are present). This hard deletes each string using *DisposeStr* (§484).

```

destructor MStringList.Done;
  var I : integer;
  begin inherited Done;
  for I ← 0 to fCount – 1 do ⟨ Hard delete entry I 456 ⟩;
  fCount ← 0; SetCapacity(0);
  end;

```

```

456. ⟨ Hard delete entry I 456 ⟩ ≡
  with fList↑[I] do { free fList↑[I] }
    begin DisposeStr(fString);
    if fObject ≠ nil then Dispose(fObject, Done);
  end

```

This code is used in section 455.

457. Adding a string. This boils down to determining the position where we will insert the new string, then inserting the string into that location, and finally returning the index to the user.

⟨String list implementation 454⟩ +≡

```
function MStringList.AddString(const aStr: string): integer;
  var lResult: integer;
  begin ⟨Set lResult to the index of the newly inserted string 458⟩;
    InsertItem(lResult, aStr); AddString ← lResult;
  end;
```

458. Determining the index for the string boils down to whether the collection is sorted or not. If it is unsorted, then just append the string at the end of the collection.

For sorted collections, find the location for the string. We need to give particular care when adding the new string would create a duplicate entry in the string list.

⟨Set *lResult* to the index of the newly inserted string 458⟩ ≡

```
if ¬fSorted then lResult ← fCount
else if Find(aStr, lResult) then
  begin AddString ← lResult; ⟨De-duplicate a string list 459⟩;
  end
```

This code is used in section 457.

459. When we ignore duplicates (i.e., the *fDuplicate* flag is equal to *dupIgnore*), we can just terminate adding a string to the collection here.

But when we want to flag an error upon inserting a duplicate entry, then we should raise an error.

All other situations “fall through”.

⟨De-duplicate a string list 459⟩ ≡

```
case fDuplicate of
  dupIgnore: Exit;
  dupError: StringListError(coDuplicate, 0);
endcases
```

This code is used in section 458.

460. Inserting an object. We can treat a string list as a dictionary whose keys are strings. This is because the entries are string-(pointer to object) pairs.

⟨String list implementation 454⟩ +≡

```
function MStringList.AddObject(const aStr: string; aObject: PObject): integer;
  var lResult: integer;
  begin lResult ← AddString(aStr); { Insert key }
    PutObject(lResult, aObject); { Insert value }
    AddObject ← lResult; { Return index }
  end;
```

461. Merging a string list. We can add all the entries from another *MStringList* to the caller, which is what we do in the *AddStrings* function. It does not mutate *aStrings*.

```
procedure MStringList.AddStrings(var aStrings : MStringList);
  var I, r: integer;
  begin for I ← 0 to aStrings.fCount − 1 do
    r ← AddObject(aStrings.fList↑[I].fString↑, aStrings.fList↑[I].fObject);
  end;
```

462. Clear a string list. We can hard delete all the strings from a string list. This *will not* free the “values” in each key-value pair.

```

procedure MStringList.Clear;
  var I: integer;
  begin if fCount  $\neq$  0 then
    begin for I  $\leftarrow$  0 to fCount - 1 do DisposeStr(fList↑[I].fString);
    fCount  $\leftarrow$  0; SetCapacity(0);
    end;
  end;

```

463. Hard delete an entry by index. When given an index which is within the bounds of the caller, we free the string located at that index, decrement the size, and then shift all entries after it down by one.

```

  define assert_valid_index(#)  $\equiv$  if (# < 0)  $\vee$  (#  $\geq$  fCount) then StringListError(coIndexError, #)
procedure MStringList.Delete(aIndex : integer);
  begin assert_valid_index(aIndex); DisposeStr(fList↑[aIndex].fString); dec(fCount);
  if aIndex < fCount then
    Move(fList↑[aIndex + 1], fList↑[aIndex], (fCount - aIndex) * SizeOf(MStringItem));
  end;

```

464. Exchanging items. We have *Exchange* check if the indices are within the bounds of the string list, then *ExchangeItems* swaps the items around.

```

procedure MStringList.Exchange(Index1, Index2 : integer);
  begin assert_valid_index(Index1); assert_valid_index(Index2); ExchangeItems(Index1, Index2);
  end;

procedure MStringList.ExchangeItems(Index1, Index2 : integer);
  var Temp: MStringItem;
  begin Temp  $\leftarrow$  fList↑[Index1]; fList↑[Index1]  $\leftarrow$  fList↑[Index2]; fList↑[Index2]  $\leftarrow$  Temp;
  end;

```

465. Find an entry by bisection search. We can use bisection search to find the needle in the haystack. Note that this implementation seeks the *leftmost occurrence* of the needle when duplicates are allowed.

[[The **if** *fDuplicate* \neq *dupAccept* statement should have an **else** branch to break the loop, to avoid needless searching.]]

```

function MStringList.Find ( const aStr: string; var aIndex: integer ) : Boolean;
  var L, H, I, C: integer; lResult: Boolean;
  begin lResult  $\leftarrow$  False; L  $\leftarrow$  0; H  $\leftarrow$  fCount - 1;
  while L  $\leq$  H do
    begin I  $\leftarrow$  (L + H) shr 1; C  $\leftarrow$  CompareStr(fList↑[I].fString↑, aStr);
    if C < 0 then L  $\leftarrow$  I + 1
    else begin { current item in haystack  $\geq$  aStr }
      H  $\leftarrow$  I - 1; { so look in left-half of haystack }
      if C = 0 then
        begin lResult  $\leftarrow$  True;
        if fDuplicate  $\neq$  dupAccept then L  $\leftarrow$  I;
        end;
      end;
    end;
  end;
  aIndex  $\leftarrow$  L; Find  $\leftarrow$  lResult;
end;

```

466. Reporting errors. We can propagate errors, adjusting the error code as needed. The comment here is in Polish “poprawic bledy” (which Google translates to “correct the errors”)

```

procedure MStringList.StringListError(Code, Info : integer);
  begin RunError(212 − Code);  {! poprawic bledy }
  end;

```

467. Getting the string at an index. When given an index within bounds, we try to get the string located there. If there is no string located at that entry, return the empty string.

```

function MStringList.GetString(aIndex : integer): string;
  begin assert_valid_index(aIndex); GetString ← ``;
  if fList↑[aIndex].fString ≠ nil then GetString ← fList↑[aIndex].fString↑;
  end;

```

468. Get object at index. We can get the object at an index, provided it is within bounds.

```

function MStringList.GetObject(aIndex : integer): PObject;
  begin assert_valid_index(aIndex); GetObject ← fList↑[aIndex].fObject;
  end;

```

469. Ensure capacity for string lists. The growth rate for string lists differs from the earlier discussion on the growth rate for dynamic arrays. Well, actually, recalling our discussion (§324), we find this is identical to the previous growth rate. So I am not sure why this code is duplicated.

```

procedure MStringList.Grow;
  var Delta: integer;
  begin if fCapacity > 64 then Delta ← fCapacity div 4
  else if fCapacity > 8 then Delta ← 16
    else Delta ← 4;
  SetCapacity(fCapacity + Delta);
  end;

```

470. Index of a string. There are two branches to this function: one for unsorted string lists, the second for sorted string lists.

```

function MStringList.IndexOf(const aStr: string): integer;
  var lResult: integer;
  begin if ¬fSorted then
    begin for lResult ← 0 to fCount − 1 do
      if CompareStr(fList↑[lResult].fString↑, aStr) = 0 then
        begin IndexOf ← lResult; Exit; end;
    lResult ← −1;
  end
  else if ¬Find(aStr, lResult) then lResult ← −1;
  { Assert: lResult = −1 if aStr is not in the caller }
  IndexOf ← lResult;
  end;

```

471. Value for a key. This appears to duplicate code from *GetObject* (§468).

```

function MStringList.ObjectOf(const aStr: string): PObject;
  var I: integer;
  begin ObjectOf ← nil; I ← IndexOf(aStr);
  if I ≥ 0 then ObjectOf ← fList↑[I].fObject;
  end;

```

472. Insert a string at an index. This seems to involve duplicate code as *AddString* (§457), but allows duplicate entries (which might violate the invariants of a string list).

```

procedure MStringList.Insert(aIndex : integer ; const aStr : string);
  begin if fSorted then StringListError(coSortedListError, 0);
    assert_valid_index(aIndex); InsertItem(aIndex, aStr);
  end;

```

473. Inserting an item at an index. We ensure the capacity of the string list. Then we shift the entries to the right by 1, if needed. We insert the string associated with no object. Then increment the logical size of the dynamic array.

There is a mirage the reader must take care about: although it superficially appears like there's bug here when the user gives $aIndex > fCapacity$, this private method is called only after checking the index is within bounds.

This procedure appears not to be used anywhere.

```

  { REQUIRES: aIndex is within bounds }
procedure MStringList.InsertItem(aIndex : integer ; const aStr : string); { private }
  begin if fCount = fCapacity then Grow;
    { Shift existing entries to right by 1 }
  if aIndex < fCount then
    Move(fList↑[aIndex], fList↑[aIndex + 1], (fCount - aIndex) * SizeOf(MStringItem));
  with fList↑[aIndex] do
    begin fObject ← nil; fString ← NewStr(aStr); end;
  inc(fCount);
end;

```

474. Find the index for an object. Find the first instance of a key-value entry whose value is equal to the given object. If the given object is absent from the string list, return -1 .

```

function MStringList.IndexOfObject(aObject : PObject): integer;
  var lResult : integer;
  begin for lResult ← 0 to fCount - 1 do
    if GetObject(lResult) = aObject then
      begin IndexOfObject ← lResult; Exit; end;
  IndexOfObject ←  $-1$ ;
end;

```

475. Insert a key-value entry at a specific index.

```

procedure MStringList.InsertObject(aIndex : integer ; const aStr : string ; aObject : PObject);
  begin Insert(aIndex, aStr); PutObject(aIndex, aObject);
end;

```

476. Moving a key-value entry around. We can take the key-value entry at *CurIndex*, remove it from the string list, then insert it at *NewIndex*. It is important to note: the *NewIndex* is the index *after* the delete operation has occurred.

```

procedure MStringList.MoveObject(CurIndex, NewIndex : integer);
  var TempObject : PObject; TempString : string;
  begin if CurIndex ≠ NewIndex then
    begin TempString ← GetString(CurIndex); TempObject ← GetObject(CurIndex);
      Delete(CurIndex); InsertObject(NewIndex, TempString, TempObject);
    end;
  end;

```

477. Inserting a string at an index. Well, if this is a sorted collection, then raise an error: you can't insert strings willy-nilly!

Then check the index is within bounds, raise an error for out-of-bounds indices.

Then mutate the entry at $aIndex$ to have its string be equal to $NewStr(aStr)$.

This will always mutate the caller, even when the string located at the entry indexed by $aIndex$ is identical to $aStr$.

```
procedure MStringList.PutString( $aIndex$  : integer ; const  $aStr$ : string);
begin if  $fSorted$  then StringListError(coSortedListError, 0);
  assert_valid_index( $aIndex$ );  $fList↑[aIndex].fString ← NewStr(aStr)$ ;
end;
```

478. Inserting an object at an index. When given an index within bounds of the caller's underlying array, mutate its object to be the given $aObject$. Again, this *always* mutates the caller.

```
procedure MStringList.PutObject( $aIndex$  : integer;  $aObject$  : PObject);
begin assert_valid_index( $aIndex$ );  $fList↑[aIndex].fObject ← aObject$ ;
end;
```

479. Quicksorting a string list. We have discussed quicksort to death earlier (§398), so I will omit the discussion. Also, quicksort occurs in one other place (§553).

```
procedure MStringList.QuickSort( $L, R$  : integer);
var  $I, J$ : integer;  $P$ : string;
begin repeat  $I ← L$ ;  $J ← R$ ;  $P ← fList↑[(L + R) shr 1].fString↑$ ;
  repeat while CompareStr( $fList↑[I].fString↑, P$ ) < 0 do  $inc(I)$ ;
    while CompareStr( $fList↑[J].fString↑, P$ ) > 0 do  $dec(J)$ ;
    { Invariant: for  $0 ≤ h < I$  we have CompareStr( $fList↑[h].fString↑, P$ ) < 0 }
    { Invariant: for  $J < k ≤ Count - 1$  we have CompareStr( $fList↑[k].fString↑, P$ ) > 0 }
    if  $I ≤ J$  then
      begin ExchangeItems( $I, J$ );  $inc(I)$ ;  $dec(J)$ ; end;
      { Invariants: for  $0 ≤ h ≤ I$  we have CompareStr( $fList↑[h].fString↑, P$ ) < 0 }
      { Invariant: for  $J ≤ k ≤ Count - 1$  we have CompareStr( $fList↑[k].fString↑, P$ ) > 0 }
    until  $I > J$ ;
    if  $L < J$  then QuickSort( $L, J$ ); { quicksort the left half }
     $L ← I$ ; { quicksort the right half }
  until  $I ≥ R$ ;
end;
```

480. Changing the capacity of a string list. Of particular note here, changing the capacity of a string list *does not* delete anything. That work must be delegated elsewhere when $aCapacity < Self.fCapacity$ (if that case ever occurs).

```

procedure MStringList.SetCapacity( $aCapacity$  : integer);
  var lList: PStringItemList;
  begin if  $aCapacity < fCount$  then  $aCapacity \leftarrow fCount$ ;
  if  $aCapacity > MaxListSize$  then  $aCapacity \leftarrow MaxListSize$ ;
  if  $aCapacity \neq fCapacity$  then
    begin if  $aCapacity = 0$  then  $lList \leftarrow \text{nil}$ 
    else begin GetMem( $lList, aCapacity * \text{SizeOf}(MStringItem)$ );
      if ( $fCount \neq 0$ )  $\wedge$  ( $fList \neq \text{nil}$ ) then Move( $fList \uparrow, lList \uparrow, fCount * \text{SizeOf}(MStringItem)$ );
      end;
    if  $fCapacity \neq 0$  then FreeMem( $fList, fCapacity * \text{SizeOf}(MStringItem)$ );
     $fList \leftarrow lList$ ;  $fCapacity \leftarrow aCapacity$ ;
    end; { ReallocMem( $fList, NewCapacity * \text{SizeOf}(MStringItem)$ );  $fCapacity := NewCapacity$ ; }
  end;

```

481. Toggle ‘sorted’ flag. Allow the user to toggle the “sorted” flag. When toggled to *True*, be sure to sort the string list.

```

procedure MStringList.SetSorted( $aValue$  : Boolean);
  begin if  $fSorted \neq aValue$  then
    begin if  $aValue$  then Sort;
     $fSorted \leftarrow aValue$ ;
    end;
  end;

```

482. Sorting. This is a wrapper around the quicksort function (§479), invoked when the *fSorted* flag is false.

This appears to be used in the *SetSorted* procedure, but that is not used anywhere.

```

procedure MStringList.Sort;
  begin if  $\neg fSorted \wedge (fCount > 1)$  then
    begin  $fSorted \leftarrow \text{true}$ ; QuickSort(0,  $fCount - 1$ );
    end;
  end;

```

483. Allocating a new string. Allocating a new *PString* from a string. When the empty string is given, return *nil*. Otherwise allocate a new block of memory in the Heap, then set its contents equal to *S*.

{ Dynamic string handling routines }

```

function NewStr(const  $S$ : string): PString;
  var P: PString;
  begin if  $S = ''$  then  $P \leftarrow \text{nil}$ 
  else begin GetMem( $P, \text{length}(S) + 1$ );  $P \uparrow \leftarrow S$ ;
  end;
   $NewStr \leftarrow P$ ;
  end;

```

484. Deleting a string. A convenience function to avoid accidentally freeing a *nil* string pointer.

```

procedure DisposeStr( $P$  : PString);
  begin if  $P \neq \text{nil}$  then FreeMem( $P, \text{length}(P \uparrow) + 1$ );
  end;

```

Section 10.14. TUPLES OF INTEGERS

485. The remainder of `mobjects.pas` focuses on finite sets of integers, finite maps of integers, and similar structures for tuples of integers. We introduce a collection of pairs of integers *specifically* to introduce the *IntRel* subclass (needed for the Equalizer, Analyzer, and Identify modules).

Also, despite the name “sequence”, we should resist the intuition of “sequences from Mathematical Analysis” like $x_n = (-1)^n/n!$. Instead we should “think like programmers” and use the computer science intuition that a “sequence is a [finite] list”.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  { Partial integers Functions }
  IntTriplet = record X1, X2, Y: integer;
  end;
const MaxIntPairSize = MaxSize div SizeOf(IntPair);
  MaxIntTripletSize = MaxSize div SizeOf(IntTriplet);

```

486. Now, this is the remainder of the interface

```

⟨Public interface for mobjects.pas 310⟩ +≡
type IntPairListPtr = ↑IntPairList;
  IntPairList = array [0 .. MaxIntPairSize - 1] of IntPair;
  IntPairSeqPtr = ↑IntPairSeq;
  IntPairSeq = object (MObject)
    Items: IntPairListPtr;
    Count: integer; { logical size }
    Limit: integer; { capacity }
    constructor Init(aLimit : integer);
    procedure NatSetError(Code, Info : integer); virtual;
    destructor Done; virtual;
    procedure SetLimit(aLimit : integer); virtual;
    procedure Insert(const aItem: IntPair); virtual;
    procedure AtDelete(aIndex : integer);
    procedure DeleteAll;
    procedure AssignPair(X, Y : integer); virtual;
  end ;

```

487. First, we have a helper function for flagging errors. This should be a protected method, since it’s used internally by the *IntPairList* class and its subclasses but *should not* be used by anyone else.

```

⟨Tuples of integers 487⟩ ≡
  { Pairs of an integers }
procedure IntPairSeq.NatSetError(Code, Info : integer);
  begin RunError(212 - Code); end;

```

See also sections 488, 489, 490, 491, 492, 495, and 496.

488. Constructor. The empty sequence constructor, initialized to have its capacity be *aLimit*. Note that *SetLimit* ensures *aLimit* is non-negative (the *SetLimit* method will not allow $aLimit < Count$ and, if this occurs, updates $aLimit \leftarrow Count$).

```

⟨Tuples of integers 487⟩ +≡
constructor IntPairSeq.Init(aLimit : integer);
  begin MObject.Init; Items ← nil; Count ← 0; Limit ← 0; SetLimit(aLimit);
  end;

```

489. Destructor. Hard delete the contents of the caller. Specifically, this will free the array of pointers, but not dispose the objects whose addresses are stored in the pointers.

```

⟨Tuples of integers 487⟩ +≡
destructor IntPairSeq.Done;
  begin Count ← 0; SetLimit(0);
  end;

```

490. Insert an element. We begin by asserting the logical size is less than the *MaxIntPairSize*. We ensure the capacity of the caller's array. Then we append the *IntPair* to the collection of items, and increment the logical size of the caller's array. No sorting occurs. Duplicates are allowed.

```

⟨Tuples of integers 487⟩ +≡
procedure IntPairSeq.Insert(const aItem: IntPair);
  begin if Count ≥ MaxIntPairSize then NatSetError(coOverflow, 0);
  if Limit = Count then SetLimit(Limit + GrowLimit(Limit));
  Items↑[Count] ← aItem; inc(Count);
  end;

```

491. Soft delete an element at an index. We soft delete an element by a specific index. We assert the index is valid. Assuming so, if the index is not the last element, we just shift all entries in the underlying array to the left by one. Then we decrement the logical size of the caller.

```

  define assert_valid_index_for_nat_set(#) ≡
    if (# < 0) ∨ (# > Count) then
      begin NatSetError(coIndexError, 0); exit; end
⟨Tuples of integers 487⟩ +≡
procedure IntPairSeq.AtDelete(aIndex : integer);
  var i: integer;
  begin assert_valid_index_for_nat_set(aIndex);
  if aIndex < Count − 1 then { shift everything to left by 1 }
    for i ← aIndex to Count − 2 do Items↑[i] ← Items↑[i + 1];
  dec(Count);
  end;

```

492. Ensure capacity for an IntPair sequence. As per usual, when ensuring the capacity of a dynamic array, we monotonically increase its size. We can use this to delete all elements of the array by manually assigning the logical size *Count* ← 0 before invoking *SetLimit*(0).

```

⟨Tuples of integers 487⟩ +≡
procedure IntPairSeq.SetLimit(aLimit : integer);
  var aItems: IntPairListPtr;
  begin { ensure Count ≤ aLimit ≤ MaxIntPairSize }
  if aLimit < Count then aLimit ← Count;
  if aLimit > MaxIntPairSize then ALimit ← MaxIntPairSize;
  if aLimit ≠ Limit then
    begin if ALimit = 0 then ALimit ← nil
    else { Allocate a new array for IntPairSeq, and copy the contents over 493 };
    { Free the old array, if it isn't nil 494 };
    Items ← aItems; Limit ← aLimit;
    end;
  end;

```

493. \langle Allocate a new array for *IntPairSeq*, and copy the contents over 493 $\rangle \equiv$
begin *GetMem*(*AItems*, *ALimit* * *SizeOf*(*IntPair*));
if (*Count* \neq 0) \wedge (*Items* \neq **nil**) **then** *Move*(*Items* \uparrow , *aItems* \uparrow , *Count* * *SizeOf*(*IntPair*));
end

This code is used in section 492.

494. \langle Free the old array, if it isn't **nil** 494 $\rangle \equiv$
if *Limit* \neq 0 **then** *FreeMem*(*Items*, *Limit* * *SizeOf*(*IntPair*))

This code is used in section 492.

495. Soft delete all entries. We just set the logical size to zero. It leaves everything else untouched.

\langle Tuples of integers 487 $\rangle + \equiv$
procedure *IntPairSeq.DeleteAll*;
begin *Count* \leftarrow 0; **end**;

496. Append a pair of integers. We create a new *IntPair* using *X* and *Y*, then append it to the caller.

\langle Tuples of integers 487 $\rangle + \equiv$
procedure *IntPairSeq.AssignPair*(*X*, *Y* : *integer*);
var *lntPair* : *IntPair*;
begin *lntPair.X* \leftarrow *X*; *lntPair.Y* \leftarrow *Y*; *Insert*(*lntPair*);
end;

Section 10.15. RELATIONS OF INTEGERS AS FINITE SETS

497. The basic idea is we want have a finite relation over integers $R \subseteq \mathbf{Z} \times \mathbf{Z}$ implemented in PASCAL as a sorted finite list of *IntPair* objects. One possible use for such a thing: we will translate identifiers into numbers (think “de Bruijn indices”), and we want to track attribute implication. This could be handled with an *IntRel* object.

This is used in the `iocorrel.pas`, `identify.pas`, the Equalizer, the Analyzer, and a polynomial library.

⟨Public interface for `mobjects.pas` 310⟩ +≡

```
IntRelPtr = ↑IntRel;
IntRel = object (IntPairSeq)
  constructor Init(aLimit : integer);
  procedure Insert(const aItem: IntPair); virtual;
  procedure AtInsert(aIndex : integer ; const aItem: IntPair); virtual;
  function Search(X, Y : integer; var aIndex : integer): Boolean; virtual;
  function IndexOf(X, Y : integer): integer;
  constructor CopyIntRel(var aFunc : IntRel);
  function IsMember(X, Y : integer): Boolean; virtual;
  procedure AssignPair(X, Y : integer); virtual;
end ;
```

498. Constructor. This is just the inherited constructor (§488).

⟨Int relation implementation 498⟩ ≡

```
{ IntRel }
constructor IntRel.Init(aLimit : integer);
  begin inherited Init(aLimit);
  end;
```

See also sections 499, 500, 501, 502, 503, 504, and 505.

This code is used in section 309.

499. Inserting an entry. Since we are trying to describe a binary relation of integers, we want to avoid duplicate entries in the underlying array. So we need to check that *aItem* is not already present in the caller’s array, and then (assuming its absence) insert the item.

An important invariant: If the caller’s array of *Items* was sorted before this function was called, then it will remain sorted after the function has returned control to the caller.

⟨Int relation implementation 498⟩ +≡

```
procedure IntRel.Insert(const aItem: IntPair);
  var I: integer;
  begin if ¬Search(aItem.X, aItem.Y, I) then
    begin { Assert: index I must be within bounds }
      assert_valid_index_for_nat_set(I);
      { Note: this should be AtInsert(I, aItem) }
      if Count ≥ MaxIntPairSize then NatSetError(coOverflow, 0);
      { Finished with the possible errors }
      if Limit = Count then SetLimit(Limit + GrowLimit(Limit));
      if I ≠ Count then Move(Items↑[I], Items↑[I + 1], (Count - I) * SizeOf(IntPair));
      Items↑[I] ← aItem; inc(Count);
    end;
  end;
```

500. Insert at a specific index. We can insert an entry at a specific location in the underlying array, but this breaks the contract that the underlying array is sorted using the *CompareIntPairs* function. This violates the assumption underlying the *Search* function.

It is used by the `polynom.pas` module, so we can't just ignore it.

⟨Int relation implementation 498⟩ +≡

```
procedure IntRel.AtInsert(aIndex : integer ; const aItem: IntPair);
begin assert_valid_index_for_nat_set(aIndex);
if Count = Limit then SetLimit(Limit + GrowLimit(Limit));
    { Shift everything to the right by 1 }
if aIndex < Limit then Move(Items↑[aIndex], Items↑[aIndex + 1], (Count - aIndex) * SizeOf(IntPair));
    { Update the items, increment the logical size }
    Items↑[aIndex] ← aItem; inc(Count);
end;
```

501. Bisection search for a relation. Search through *IntRel* for an entry (X, Y). Note that this is not symmetric, i.e., if we have (Y, X) in the *IntRel*, then it will not match.

Mutates the *aIndex*. If the relation is missing, *aIndex* will return where it *should* be.

Assumes the underlying array is sorted using *CompareIntPairs*.

⟨Int relation implementation 498⟩ +≡

```
function IntRel.Search(X, Y : integer; var aIndex : integer): Boolean;
var L, H, I, C: integer;
begin Search ← False; L ← 0; H ← Count - 1;
while L ≤ H do
    begin I ← (L + H) shr 1; C ← CompareIntPairs(Items↑[I].X, Items↑[I].Y, X, Y);
    if C < 0 then L ← I + 1
    else begin H ← I - 1;
        if C = 0 then
            begin Search ← True; L ← I; end;
        end;
    end;
aIndex ← L;
end;
```

502. Copy constructor. This moves the contents of *aFunc* into the caller. It will mutate the caller *but not* the argument supplied. The *Move* function copies the contents of one region of memory to another.

⟨Int relation implementation 498⟩ +≡

```
constructor IntRel.CopyIntRel(var aFunc : IntRel);
begin Init(aFunc.Limit); Move(aFunc.Items↑, Items↑, aFunc.Limit * SizeOf(IntPair));
    Count ← aFunc.Count;
end;
```

503. Index of a relation. This will return the index of the (X, Y) entry. If it is absent from the caller, then return -1.

⟨Int relation implementation 498⟩ +≡

```
function IntRel.IndexOf(X, Y : integer): integer;
var I: integer;
begin IndexOf ← -1;
if Search(X, Y, I) then IndexOf ← I;
end;
```

504. Test for membership. This just tests if (X, Y) is contained in the caller.

⟨Int relation implementation 498⟩ +≡

```
function IntRel.IsMember(X, Y : integer): Boolean;
  var I : integer;
  begin IsMember  $\leftarrow$  Search(X, Y, I); end;
```

505. If (X, Y) belongs to the caller, then we're good: we do not need to do anything. Otherwise, the parent class's *AssignPair* (§496) method is invoked, which will just invoke the *Insert* method for inserting the pair to the caller.

An important invariant: if the array of *Items* is sorted before the function is called, then it remains sorted when this function is terminated.

⟨Int relation implementation 498⟩ +≡

```
procedure IntRel.AssignPair(X, Y : integer);
  begin if IsMember(X, Y) then exit;
  inherited AssignPair(X, Y);
  end;
```

Section 10.16. FINITE SETS OF INTEGERS

506. We treat a finite relation of integers as a set, ignoring the second component of the entries, assigning them to zero when inserting a number. So we have $\{(x, 0), \dots, (x', 0)\}$ encoded by a sorted array of integer pairs.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  NatSetPtr = ↑NatSet;
  NatSet = object (IntRel)
    Delta: integer;
    Duplicates: Boolean;
    constructor Init(aLimit, aDelta : integer);
    constructor InitWithElement(X : integer);
    destructor Done; virtual;
    procedure Insert(const aItem: IntPair); virtual;
    function SearchPair(X : integer; var Index : integer): Boolean; virtual;
    function ElemNr(X : integer): integer;
      { ***** }
    constructor CopyNatSet(const fFunc: NatSet);
    procedure InsertElem(X : integer); virtual;
    procedure DeleteElem(fElem : integer); virtual;
    procedure EnlargeBy(const fAnother: NatSet); { ? virtual;? }

    procedure ComplementOf(const fAnother: NatSet);
    procedure IntersectWith(const fAnother: NatSet);
      { ***** }
    function HasInDom(fElem : integer): Boolean; virtual;
    function IsEqualTo(const fFunc: NatSet): Boolean;
    function IsSubsetOf(const fFunc: NatSet): Boolean;
    function IsSupersetOf(const fFunc: NatSet): Boolean;
    function Misses(const fFunc: NatSet): Boolean;
    constructor MoveNatSet(var fFunc : NatSet);
  end ;

```

507. Constructor. The empty *NatSet* can be constructed with the usual initialization.

```

⟨Partial integer function implementation 507⟩ ≡
  { Partial integers Functions }
constructor NatSet.Init(aLimit, aDelta : integer);
  begin MObject.Init; Items ← nil; Count ← 0; Limit ← 0; Delta ← ADelta; SetLimit(ALimit);
  Duplicates ← False;
end;

```

See also section 527.

This code is used in section 309.

508. Singleton constructor. This initializes the *Delta* set to 4, and the *aLimit* set to 0. Then insert the given integer.

```

constructor NatSet.InitWithElement(X : integer);
  begin Init(0, 4); InsertElem(X);
end;

```

509. Destructor. This delegates the heavy work to *SetLimit*(0).

```

destructor NatSet.Done;
  begin Count  $\leftarrow$  0; SetLimit(0);
  end;

```

510. Inserting a pair of integers. Using *Search* to find where to insert $X = Y$, possibly growing the underlying array if needed.

```

procedure NatSet.Insert(const aItem: IntPair);
  var I: integer;
  begin if  $\neg$ SearchPair(aItem.X, I)  $\vee$  Duplicates then
    begin assert_valid_index_for_nat_set(I);
    if Limit = Count then { Grow the capacity, if possible }
      begin if Delta = 0 then
        begin NatSetError(coOverflow, 0); exit; end;
        SetLimit(Limit + Delta);
      end;
    if  $I \neq$  Count then Move(Items $\uparrow$ [I], Items $\uparrow$ [I + 1], (Count - I) * SizeOf(IntPair));
    Items $\uparrow$ [I]  $\leftarrow$  aItem; inc(Count);
  end;
end;

```

511. Equality of IntPair objects. This private function just tests the componentwise equality of two *IntPair* objects.

```

function Equals(Key1, Key2 : IntPair): Boolean;
  begin Equals  $\leftarrow$  (Key1.X = Key2.X)  $\wedge$  (Key1.Y = Key2.Y);
  end;

```

512. Search. This is a bisection search for any relation of the form (X, Y) for some Y . Assumes the array is sorted by the first component.

```

function NatSet.SearchPair(X : integer; var Index : integer): Boolean;
  var L, H, I, C: integer;
  begin SearchPair  $\leftarrow$  False; L  $\leftarrow$  0; H  $\leftarrow$  Count - 1;
  while  $L \leq H$  do
    begin I  $\leftarrow$  (L + H) shr 1; C  $\leftarrow$  CompareInt(Items $\uparrow$ [I].X, X);
    if  $C < 0$  then L  $\leftarrow$  I + 1
    else begin H  $\leftarrow$  I - 1;
      if  $C = 0$  then
        begin SearchPair  $\leftarrow$  True;
        if  $\neg$ Duplicates then L  $\leftarrow$  I;
        end;
      end;
    end;
  end;
  Index  $\leftarrow$  L;
end;

```

513. Copy constructor. We can copy the contents of another *NatSet* into the caller. This mutates the caller, but leaves the given *NatSet* unchanged.

```

constructor NatSet.CopyNatSet(const fFunc: NatSet);
  begin Init(fFunc.Limit, fFunc.Delta); Move(fFunc.Items $\uparrow$ , Items $\uparrow$ , fFunc.Limit * SizeOf(IntPair));
  Count  $\leftarrow$  fFunc.Count;
  end;

```

514. Move constructor. We can also *move* the contents of another *NatSet* into the caller. This will mutate the other *NatSet* to have **nil** items and 0 capacity.

```
constructor NatSet.MoveNatSet(var fFunc : NatSet);
  begin Init(fFunc.Limit, fFunc.Delta); Self  $\leftarrow$  fFunc; fFunc.DeleteAll; fFunc.Limit  $\leftarrow$  0;
  fFunc.Items  $\leftarrow$  nil;
end;
```

515. Union operation. We can merge another *NatSet* into the caller.

```
procedure NatSet.EnlargeBy(const fAnother : NatSet);
  var I : integer;
  begin for I  $\leftarrow$  0 to fAnother.Count - 1 do InsertElem(fAnother.Items $\uparrow$ [i].X);
end;
```

516. Set complement. We can destructively remove from the caller all elements appearing in *fAnother* nat set.

```
procedure NatSet.ComplementOf(const fAnother : NatSet);
  var I : integer;
  begin for I  $\leftarrow$  0 to fAnother.Count - 1 do DeleteElem(fAnother.Items $\uparrow$ [i].X);
end;
```

517. Take intersection. This computes $Self \leftarrow Self \cap Other$

```
procedure NatSet.IntersectWith(const fAnother : NatSet);
  var k : integer;
  begin k  $\leftarrow$  0;
  while k < Count do
    if  $\neg$ fAnother.HasInDom(Items $\uparrow$ [k].X) then AtDelete(k)
    else inc(k);
  end;
```

518. Insert an element. We can insert $(X, 0)$ into the caller.

```
procedure NatSet.InsertElem(X : integer);
  var UntPair : IntPair;
  begin UntPair.X  $\leftarrow$  X; UntPair.Y  $\leftarrow$  0; Insert(UntPair);
end;
```

519. Deleting an element. Similarly, we can delete the first element of the form (X, Y) for some *Y*.

```
procedure NatSet.DeleteElem(fElem : integer);
  var I : integer;
  begin if SearchPair(fElem, I) then AtDelete(I);
end;
```

520. We can test if an element *X* is in the domain of the caller.

```
function NatSet.HasInDom(fElem : integer): Boolean;
  var I : integer;
  begin HasInDom  $\leftarrow$  SearchPair(fElem, I);
end;
```

521. Set equality predicate. This assumes that there are no duplicate entries in a *NatSet* data structure.

```
function NatSet.IsEqualTo(const fFunc: NatSet): Boolean;
  var I: integer;
  begin IsEqualTo ← false;
  if Count ≠ fFunc.Count then exit;
  for I ← 0 to Count - 1 do
    if ¬Equals(Items↑[I], fFunc.Items↑[I]) then exit;
  IsEqualTo ← true;
end;
```

522. Subset predicate. The comment is Polish for (according to Google translate): “If we’re checking if a small function is contained within a large one, commenting it out might be better.” There is a commented out function which I removed.

```
function NatSet.IsSubsetOf(const fFunc: NatSet): Boolean;
  var i, j, k, c: integer; { Jezeli sprawdzamy, czy mala funkcja jest zawarta w duzej, to to wykomentowane
                           moze byc lepsze }
  begin IsSubsetOf ← false; c ← fFunc.Count;
  if c < Count then exit;
  j ← 0;
  for i ← 0 to Count - 1 do
    begin k ← Items↑[i].X;
    while (j < c) ∧ (fFunc.Items↑[j].X < k) do inc(j);
    if (j = c) ∨ ¬Equals(fFunc.Items↑[j], Items↑[i]) then exit;
    end;
  IsSubsetOf ← true;
end;
```

523. Superset predicate. This just takes advantage of the fact that $Y \supseteq X$ is the same as $X \subseteq Y$, then use the subset predicate.

```
function NatSet.IsSupersetOf(const fFunc: NatSet): Boolean;
  begin IsSupersetOf ← fFunc.IsSubsetOf(Self);
end;
```

524. Test if two sets are disjoint. This iterates over the smaller of the two sets, checking if every element in the smaller set *does not* appear in the larger set.

```
function NatSet.Misses(const fFunc: NatSet): Boolean;
  var I, k: integer;
  begin if Count > fFunc.Count then ⟨Return false if any item of fFunc is in Self 525⟩
  else ⟨Return false if any item of Self is in fFunc 526⟩;
  Misses ← true;
end;
```

525. ⟨Return false if any item of *fFunc* is in *Self* 525⟩ ≡

```
begin for k ← 0 to fFunc.Count - 1 do
  if SearchPair(fFunc.Items↑[k].X, I) then
    begin Misses ← false; exit end
end
```

This code is used in section 524.

526. \langle Return *false* if any item of *Self* is in *fFunc* 526 $\rangle \equiv$
begin for $k \leftarrow 0$ to $Count - 1$ **do**
 if *fFunc.SearchPair*(*Items* $\uparrow[k].X, I$) **then**
 begin *Misses* \leftarrow *false*; *exit* **end**;
end

This code is used in section 524.

527. Index for an element. This searches for the index associated with relations of the form (X, Y) . If any such relation appears, return its index. Otherwise, return -1 .

It leaves the caller unmodified, so it is a pure function.

\langle Partial integer function implementation 507 $\rangle + \equiv$
function *NatSet.ElemNr*($X : integer$): *integer*;
 var $I : integer$;
 begin *ElemNr* $\leftarrow -1$;
 if *SearchPair*(X, I) **then** *ElemNr* $\leftarrow I$;
end;

Section 10.17. FUNCTION OF NATURAL NUMBERS

528. The *NatFunc* is used in the analyzer, equalizer, unifier, and elsewhere. Its destructor is the only place where $nConsistent \leftarrow false$.

⟨Public interface for `mobjects.pas` 310⟩ \equiv

```

NatFuncPtr =  $\uparrow$ NatFunc;
NatFunc = object (NatSet)
  nConsistent: Boolean;
  constructor InitNatFunc(ALimit, ADelta : integer);
  constructor CopyNatFunc(const fFunc: NatFunc);
  constructor MoveNatFunc(var fFunc : NatFunc);
  constructor LCM(const aFunc1, aFunc2: NatFunc);
  procedure Assign(X, Y : integer); virtual;
  procedure Up(X : integer); virtual;
  procedure Down(X : integer); virtual;
  function Value(fElem : integer): integer; virtual;
  procedure Join(const fFunc: NatFunc);
  destructor Refuted; virtual;
  procedure EnlargeBy(fAnother : NatFuncPtr); { ? virtual? }

  function JoinAtom(fLatAtom : NatFuncPtr): NatFuncPtr;
  function CompareWith(const fNatFunc: NatFunc): integer;
  function WeakerThan(const fNatFunc: NatFunc): Boolean;
  function IsMultipleOf(const fNatFunc: NatFunc): Boolean;
  procedure Add(const aFunc: NatFunc);
  function CountAll: integer; virtual;
end ;

```

529. Constructors. We have the basic constructors for an empty *NatFunc*, a copy constructor, and a move constructor. The move constructor is destructive on the supplied argument.

⟨*NatFunc* implementation 529⟩ \equiv

```

constructor NatFunc.InitNatFunc(ALimit, ADelta : integer);
  begin inherited Init(ALimit, ADelta); nConsistent  $\leftarrow$  true;
  end;

constructor NatFunc.CopyNatFunc(const fFunc: NatFunc);
  begin Init(fFunc.Limit, fFunc.Delta); Move(fFunc.Items $\uparrow$ , Items $\uparrow$ , fFunc.Limit * SizeOf(IntPair));
  Count  $\leftarrow$  fFunc.Count; nConsistent  $\leftarrow$  fFunc.nConsistent;
  end;

constructor NatFunc.MoveNatFunc(var fFunc : NatFunc);
  begin Init(fFunc.Limit, fFunc.Delta); Self  $\leftarrow$  fFunc; fFunc.DeleteAll; fFunc.Limit  $\leftarrow$  0;
  fFunc.Items  $\leftarrow$  nil;
  end;

```

See also sections 534 and 546.

This code is used in section 309.

530. Constructor (LCM). The least common multiple between two *NatFunc* objects is another way to construct a *NatFunc* instance. This seems to be the LCM in the sense of commutative rings (if x and y are elements of a commutative ring R , then $\text{lcm}(x, y)$ is such that x divides $\text{lcm}(x, y)$ and y divides $\text{lcm}(x, y)$ — moreover, $\text{lcm}(x, y)$ is the smallest such quantity, in the sense that $\text{lcm}(x, y)$ divides any other such quantity).

The implementation amounts to something like,

$$\text{lcm}(f, g) = \{ (x, y) \mid \exists y_1, y_2, (x, y_1) \in f, (x, y_2) \in g, y = \max(y_1, y_2) \} \cup (f \Delta g),$$

with the condition that when $y_1 = 0$, $y = y_2$ (and similarly $y_2 = 0$ implies $y = y_1$), and the symmetric difference

$$f \Delta g = (f \setminus g) \cup (g \setminus f).$$

This is not quite the same as the least common multiple in the ring $\mathbf{N}^{\mathbf{N}}$.

```

constructor NatFunc.LCM (const aFunc1, aFunc2: NatFunc);
  var i, j, m: integer;
  begin m  $\leftarrow$  aFunc2.Delta;
  if aFunc1.Delta > m then m  $\leftarrow$  aFunc1.Delta;
  InitNatFunc(aFunc1.Limit + aFunc2.Limit, m); i  $\leftarrow$  0; j  $\leftarrow$  0;
  while (i < aFunc1.Count)  $\wedge$  (j < aFunc2.Count) do
    case CompareInt(aFunc1.Items $\uparrow$ [i].X, aFunc2.Items $\uparrow$ [j].X) of
      -1: begin Insert(aFunc1.Items $\uparrow$ [i]); inc(i) end;
      0: begin { m = max(f(i), g(i) }
          m  $\leftarrow$  aFunc1.Items $\uparrow$ [i].Y;
          if aFunc2.Items $\uparrow$ [j].Y > m then m  $\leftarrow$  aFunc2.Items $\uparrow$ [j].Y;
          Assign(aFunc1.Items $\uparrow$ [i].X, m); { destructively set f(i)  $\leftarrow$  m }
          inc(i); inc(j);
        end;
      1: begin Insert(aFunc2.Items $\uparrow$ [j]); inc(j) end;
    endcases;
  if i  $\geq$  aFunc1.Count then
    for j  $\leftarrow$  j to aFunc2.Count - 1 do Insert(aFunc2.Items $\uparrow$ [j])
  else for i  $\leftarrow$  i to aFunc1.Count - 1 do Insert(aFunc1.Items $\uparrow$ [i]);
  end;

```

531. Extend a natural function. We can extend a natural function to assign a value y to a place where it is not yet defined $x \notin \text{dom}(f)$.

We should recall *HasInDom* (§520) which depends on *SearchPair* (§512) is relevant. When trying to assign a different value y to an already defined $f(x) \neq y$, then we have refuted something.

```

procedure NatFunc.Assign(X, Y : integer);
  var UntPair: IntPair;
  begin if nConsistent then
    begin if HasInDom(X)  $\wedge$  (Value(X)  $\neq$  Y) then
      begin Refuted; exit end;
    UntPair.X  $\leftarrow$  X; UntPair.Y  $\leftarrow$  Y; Insert(UntPair);
    end;
  end;

```

532. Increment $f(x)$. Given a *NatFunc* object f , and an integer x , $f.Up(x)$ will

- (1) If $x \in \text{dom}(f)$, then update the value $f(x) \geq f(x) + 1$
- (2) Otherwise, $x \notin \text{dom}(f)$, so this corresponds to $f(x) = 0$, then we mutate $f(x) \leftarrow 1$.

```

procedure NatFunc.Up( $X : \text{integer}$ );
  var  $I : \text{integer}$ ;  $l\text{IntPair} : \text{IntPair}$ ;
  begin if  $n\text{Consistent}$  then
    begin if  $\text{SearchPair}(X, I)$  then  $\text{inc}(\text{Items}\uparrow[I].Y)$ 
    else  $\langle \text{Insert}(X, 1) \text{ 533} \rangle$ ;
    end;
  end;

```

```

533.  $\langle \text{Insert}(X, 1) \text{ 533} \rangle \equiv$ 
  begin  $l\text{IntPair}.X \leftarrow X$ ;  $l\text{IntPair}.Y \leftarrow 1$ ;  $\text{Insert}(l\text{IntPair})$ ;
  end

```

This code is used in section 532.

534. Decrement $f(x)$. Given a *NatFunc* object f , and an integer x , $f.Down(x)$ will

- (1) If $x \in \text{dom}(f)$, then update the value $f(x) \geq f(x) - 1$ and if this is then zero, remove it from the function.
- (2) Otherwise, $x \notin \text{dom}(f)$, so this corresponds to $f(x) = 0$, and we cannot mutate $f(x) \leftarrow -1$ without making it no longer natural-valued. So we raise an error.

$\langle \text{NatFunc implementation 529} \rangle + \equiv$

```

procedure NatFunc.Down( $X : \text{integer}$ );
  var  $I : \text{integer}$ ;
  begin if  $n\text{Consistent}$  then
    begin if  $\text{SearchPair}(X, I)$  then
      begin  $\text{dec}(\text{Items}\uparrow[I].Y)$ ;
      if  $\text{Items}\uparrow[I].Y = 0$  then  $\text{AtDelete}(I)$ ;
      end
    else  $\text{NatSetError}(\text{coConsistentError}, 0)$ ;
    end;
  end;

```

535. Getting the value of $f(x)$ when $x \in \text{dom}(f)$. When $x \notin \text{dom}(f)$, raise an error.

```

function NatFunc.Value( $f\text{Elem} : \text{integer}$ ):  $\text{integer}$ ;
  var  $I : \text{integer}$ ;
  begin if  $\text{SearchPair}(f\text{Elem}, I)$  then  $\text{Value} \leftarrow \text{Items}\uparrow[I].Y$ 
  else  $\text{NatSetError}(\text{coDuplicate}, 0)$ ;
  end;

```

536. Destructor. We usually try to extend partial functions on \mathbf{N} , but if we end up trying to extend where it is already defined to a different value, then we arrive at an inconsistent extension. It is referred to as a “refuted” situation.

```

destructor NatFunc.Refuted;
  begin  $\text{inherited Done}$ ;  $n\text{Consistent} \leftarrow \text{false}$ 
  end;

```

537. Join. For two partial functions $f: \mathbf{N} \rightarrow \mathbf{N}$ and $g: \mathbf{N} \rightarrow \mathbf{N}$, we form $f \cup g$ provided

$$f \cap g = f|_{\text{dom}(f \cap g)} = g|_{\text{dom}(f \cap g)}.$$

That is to say, for all $x \in \text{dom}(f) \cap \text{dom}(g)$, we have $f(x) = g(x)$.

The comment is in Polish, which Google translates as: “It seems that the *Join* and *EnlargeBy* procedures below do the same thing. *EnlargeBy* should be faster for small collections. If not, it’s not worth the code waste and can be discarded. On the other hand, these procedures are primarily intended for (very) small collections.”

Also worth observing, this tests for consistency in the other *NatFunc*.

```
{ Wyglada na to, ze ponizej podane procedury "Join" i "EnlargeBy" robia to samo, "EnlargeBy"
  powinna byc szybsza dla malych kolekcji. Jezeli tak nie jest nie warto tracic kodu i mozna ja
  wyrzucic. Z drugiej strony procedury te maja byc glownie stosowane do (bardzo) malych kolekcji. }
procedure NatFunc.Join(const fFunc: NatFunc);
var I, k: integer;
begin if nConsistent then
  begin if ¬fFunc.nConsistent then
    begin Refuted; exit end;
  for k ← 0 to fFunc.Count − 1 do
    if SearchPair(fFunc.Items↑[k].X, I) then
      begin if ¬Equals(Items↑[I], fFunc.Items↑[k]) then
        begin Refuted; exit end;
      end
    else Insert(fFunc.Items↑[k]);
  end;
end;
```

538. This function performs the same task as the previous one (i.e., it merges another partial function into the caller, provided it is consistent on overlap).

```
procedure NatFunc.EnlargeBy(fAnother : NatFuncPtr); { ? virtual;? }
var i, j, lCount, lLimit: integer; lItems: IntPairListPtr;
begin if nConsistent then
  begin if ¬fAnother↑.nConsistent then
    begin Refuted; exit end;
  if fAnother↑.Count = 0 then exit;
  lCount ← Count; lItems ← Items; lLimit ← Limit; Limit ← 0; Count ← 0;
  SetLimit(lCount + fAnother↑.Count); i ← 0; j ← 0;
  while (i < lCount) ∧ (j < fAnother↑.Count) do
    case CompareInt(lItems↑[i].X, fAnother↑.Items↑[j].X) of
      −1: begin Insert(lItems↑[i]); inc(i) end;
      0: begin if Equals(lItems↑[i], fAnother↑.Items↑[j]) then Insert(lItems↑[i])
        else begin Refuted; FreeMem(lItems, lLimit * SizeOf(IntPair)); exit end;
        inc(i); inc(j);
      end;
      1: begin Insert(fAnother↑.Items↑[j]); inc(j) end;
    endcases;
  if i ≥ lCount then
    for j ← j to fAnother↑.Count − 1 do Insert(fAnother↑.Items↑[j])
  else for i ← i to lCount − 1 do Insert(lItems↑[i]);
  SetLimit(0); FreeMem(lItems, lLimit * SizeOf(IntPair));
  end;
end;
```

539. We want to join two partial functions $f: \mathbf{N} \rightarrow \mathbf{N}$ and $g: \mathbf{N} \rightarrow \mathbf{N}$ without accidentally mutating either f or g to be refuted. To do this, we copy the caller, then enlarge it with the other partial function. If the result is consistent, then return it. Otherwise, return **nil**.

This leaves both the caller and $fLatAtom$ unchanged, so it's a pure function.

```
function NatFunc.JoinAtom(fLatAtom : NatFuncPtr): NatFuncPtr;
var lEval: NatFunc;
begin JoinAtom  $\leftarrow$  nil; lEval.CopyNatFunc(Self); lEval.EnlargeBy(fLatAtom);
if lEval.nConsistent then JoinAtom  $\leftarrow$  NatFuncPtr(lEval.CopyObject);
end;
```

540. Comparing partial functions. Given two partial functions, $f: \mathbf{N} \rightarrow \mathbf{N}$ and $g: \mathbf{N} \rightarrow \mathbf{N}$, we want to compare them. We first start with comparing $\|f\|$ against $\|g\|$. If they are not equal, then this is the result.

When $\|f\| = \|g\|$, iterate through each $x \in \text{dom}(f)$, and then compare $f(x)$ against $g(x)$. If $f(x) < g(x)$, then return -1 . If $f(x) > g(x)$, then return $+1$. Otherwise keep iterating until we have examined all of $\text{dom}(f)$, and then we return 0 .

```
function CompareNatFunc(aKey1, aKey2 : Pointer): integer;
var i, lnt: integer;
begin with NatFuncPtr(aKey1) $\uparrow$  do
  begin lnt  $\leftarrow$  CompareInt(Count, NatFuncPtr(aKey2) $\uparrow$ .Count);
  if lnt  $\neq$   $0$  then
    begin CompareNatFunc  $\leftarrow$  lnt; exit end;
  for i  $\leftarrow$   $0$  to Count  $- 1$  do
    begin lnt  $\leftarrow$  CompareInt(Items $\uparrow$ [i].X, NatFuncPtr(aKey2) $\uparrow$ .Items $\uparrow$ [i].X);
    if lnt  $\neq$   $0$  then
      begin CompareNatFunc  $\leftarrow$  lnt; exit end;
      lnt  $\leftarrow$  CompareInt(Items $\uparrow$ [i].Y, NatFuncPtr(aKey2) $\uparrow$ .Items $\uparrow$ [i].Y);
      if lnt  $\neq$   $0$  then
        begin CompareNatFunc  $\leftarrow$  lnt; exit end;
      end;
    end;
  CompareNatFunc  $\leftarrow$   $0$ ;
end;
```

541. Let $f: \mathbf{N} \rightarrow \mathbf{N}$ and $g: \mathbf{N} \rightarrow \mathbf{N}$ be partial functions. We say that f is “weaker” than g when $\|f\| \leq \|g\|$ and for each $x \in \text{dom}(f)$ we have $f(x) = g(x)$. If there is some $x \in \text{dom}(f)$ such that $x \notin \text{dom}(g)$, then f is not weaker than g .

If there is some $x \in \text{dom}(f)$ such that $x \in \text{dom}(g)$ and $f(x) \neq g(x)$, then f is not weaker than g .

```
function NatFunc.WeakerThan(const fNatFunc: NatFunc): Boolean;
var i, k: integer;
begin WeakerThan  $\leftarrow$  false;
if Count  $\leq$  fNatFunc.Count then
  begin for k  $\leftarrow$   $0$  to Count  $- 1$  do
    begin i  $\leftarrow$  Items $\uparrow$ [k].X;
    if  $\neg$ fNatFunc.HasInDom(i) then exit;
    if Items $\uparrow$ [k].Y  $\neq$  fNatFunc.Value(i) then exit;
    end;
  WeakerThan  $\leftarrow$  true;
end;
end;
```

542. Let $f: \mathbf{N} \rightarrow \mathbf{N}$ and $g: \mathbf{N} \rightarrow \mathbf{N}$ be partial functions. We will say that f is a “multiple” of g if $\|g\| \leq \|f\|$ and for each $x \in \text{dom}(g)$ we have $x \in \text{dom}(f)$ and $g(x) \leq f(x)$.

There was some commented code for this function, which I removed.

```
function NatFunc.IsMultipleOf(const fNatFunc: NatFunc): Boolean;
var k, l: integer;
begin IsMultipleOf  $\leftarrow$  false;
if fNatFunc.Count  $\leq$  Count then
  begin for k  $\leftarrow$  0 to fNatFunc.Count - 1 do
    if  $\neg$ HasInDom(fNatFunc.Items $\uparrow$ [k].X) then exit
    else if Value(fNatFunc.Items $\uparrow$ [k].X) < fNatFunc.Items $\uparrow$ [k].Y then exit;
    IsMultipleOf  $\leftarrow$  true;
  end;
end;
```

543. Comparing partial functions. Let $f: \mathbf{N} \rightarrow \mathbf{N}$ and $g: \mathbf{N} \rightarrow \mathbf{N}$ be partial functions.

If there are more elements in the caller f than the other function g , $\|f\| \leq \|g\|$, for each $x \in \text{dom}(f)$ if $x \notin \text{dom}(g)$, then return 0. If $f(x) \neq g(x)$, then return 0. Otherwise return -1.

Otherwise, if there are more elements in the other function g than the caller $\|g\| \leq \|f\|$, for each $x \in \text{dom}(g)$ if $x \notin \text{dom}(f)$, then return 0. If $f(x) \neq g(x)$, then this will return 0. Otherwise return +1.

This is difficult for me to grasp. It does not seem to adequately satisfy $\text{compare}(f, g) = -\text{compare}(g, f)$, which is catastrophic. It is also unclear to me that this is transitive or reflexive. So it seems like it has no desirable properties.

I am confused why there is this function and also another similarly named function (§540).

The comment in Polish translates as, “Using *WeakerThan* you can shorten *CompareWith*!!!” At least, according to Google, that’s the translation.

{ Uzywajac *WeakerThan* mozna skrociac *CompareWith* !!! }

```
function NatFunc.CompareWith(const fNatFunc: NatFunc): integer;
var i, k: integer;
begin CompareWith  $\leftarrow$  0;
if Count  $\leq$  fNatFunc.Count then
  begin for k  $\leftarrow$  0 to Count - 1 do
    begin i  $\leftarrow$  Items $\uparrow$ [k].X;
    if  $\neg$ fNatFunc.HasInDom(i) then exit; { returns 0 }
    if Items $\uparrow$ [k].Y  $\neq$  fNatFunc.Value(i) then exit; { returns 0 }
    end;
    CompareWith  $\leftarrow$  -1; exit;
  end;
if fNatFunc.Count  $\leq$  Count then
  begin for k  $\leftarrow$  0 to fNatFunc.Count - 1 do
    begin i  $\leftarrow$  fNatFunc.Items $\uparrow$ [k].X;
    if  $\neg$ HasInDom(i) then exit; { returns 0 }
    if fNatFunc.Items $\uparrow$ [k].Y  $\neq$  Value(i) then exit; { returns 0 }
    end;
    CompareWith  $\leftarrow$  1; exit;
  end;
end;
```

544. Let $f: \mathbf{N} \rightarrow \mathbf{N}$ and $g: \mathbf{N} \rightarrow \mathbf{N}$ be partial functions. Then we define $f + g: \mathbf{N} \rightarrow \mathbf{N}$ to be the partial function defined on $\text{dom}(f + g) = \text{dom}(f) \cup \text{dom}(g)$ such that for each $x \in \text{dom}(f \cap g)$ we have $(f + g)(x) = f(x) + g(x)$, and for each $x \in \text{dom}(f) \setminus \text{dom}(g)$ we have $(f + g)(x) = f(x)$, and for each $x \in \text{dom}(g) \setminus \text{dom}(f)$ we have $(f + g)(x) = g(x)$.

There is some subtlety in the implementation because we have to check for overflows, i.e., when

$$g(x) \geq \text{High}(\text{integer}) - f(x)$$

for each $x \in \text{dom}(f) \cap \text{dom}(g)$.

```

procedure NatFunc.Add(const aFunc: NatFunc);
  var k, l: integer;
  begin l  $\leftarrow$  0;
  for k  $\leftarrow$  0 to aFunc.Count - 1 do
    begin while (l < Count)  $\wedge$  (Items $\uparrow$ [l].X < aFunc.Items $\uparrow$ [k].X) do inc(l);
    if (l < Count)  $\wedge$  (Items $\uparrow$ [l].X = aFunc.Items $\uparrow$ [k].X) then
      begin if  $\langle$  Has overflow occurred in NatFunc.Add? 545  $\rangle$  then RunError(215);
      inc(Items $\uparrow$ [l].Y, aFunc.Items $\uparrow$ [k].Y);
      end
    else AtInsert(l, aFunc.Items $\uparrow$ [k]);
    end;
  end;

```

545. An overflow occurs if $f(x) + g(x)$ is greater than $\text{High}(\text{integer})$ (the maximum value for an integer).

\langle Has overflow occurred in *NatFunc.Add*? 545 $\rangle \equiv$
 $\text{Items}\uparrow[l].Y > (\text{High}(\text{integer}) - \text{aFunc.Items}\uparrow[k].Y)$

This code is used in section 544.

546. Sum values of partial function. For a partial function $f: \mathbf{N} \rightarrow \mathbf{N}$, we have

$$\text{CountAll}(f) = \sum_{n \in \text{dom}(f)} f(n).$$

\langle *NatFunc* implementation 529 $\rangle + \equiv$

```

function NatFunc.CountAll: integer;
  var k, l: integer;
  begin l  $\leftarrow$  0;
  for k  $\leftarrow$  0 to Count - 1 do inc(l, Items $\uparrow$ [k].Y);
  CountAll  $\leftarrow$  l;
  end;

```

Section 10.18. SEQUENCES OF NATURAL NUMBERS

547. A finite sequence of natural numbers is a kind of finite partial function between natural numbers. This is used in the `first_identification.pas`, `inlibr.pas`, and `impobjs.pas`.

⟨Public interface for `mobjects.pas` 310⟩ \equiv
`NatSeq = object (NatFunc)`
 constructor `InitNatSeq`(`ALimit`, `ADelta` : integer);
 procedure `InsertElem`(`X` : integer); *virtual*;
 function `Value`(`fElem` : integer): integer; *virtual*;
 function `IndexOf`(`Y` : integer): integer;
end ;

548. Constructor.

⟨`NatSeq` implementation 548⟩ \equiv
constructor `NatSeq.InitNatSeq`(`ALimit`, `ADelta` : integer);
 begin *inherited* `Init`(`ALimit`, `ADelta`); `nConsistent` \leftarrow *true*;
 end;

This code is used in section 309.

549. If we have a finite sequence (a_0, \dots, a_{n-1}) , then inserting an element x into it will yield the finite sequence (a_0, \dots, a_{n-1}, x) .

procedure `NatSeq.InsertElem`(`X` : integer);
 var `lPair`: *IntPair*;
 begin `lPair.X` \leftarrow *Count*; `lPair.Y` \leftarrow `X`; *inherited* `Insert`(`lPair`);
 end;

550. The value for the k^{th} element in a sequence (a_0, \dots, a_{n-1}) is a_k when $0 \leq k < n$, and we take it to be 0 otherwise.

function `NatSeq.Value`(`fElem` : integer): integer;
 begin
 if { $0 \leq \text{ind}$ } and { $\text{fElem} < \text{count}$ } **then** `Value` \leftarrow `Items` \uparrow [`fElem`].`Y`
 else `Value` \leftarrow 0;
 end ;

551. The index for a_i in the sequence (a_0, \dots, a_{n-1}) is i when a_i is in the sequence. Otherwise, we return -1 .

function `NatSeq.IndexOf`(`Y` : integer): integer;
 var `lResult`: integer;
 begin `lResult` \leftarrow `Count` - 1 **downto** 0 **do**
 if `Items` \uparrow [`lResult`].`Y` = `Y` **then**
 begin `IndexOf` \leftarrow `lResult`; *exit*
 end;
 `IndexOf` \leftarrow -1;
end;

Section 10.19. INTEGER SEQUENCES

552. Note: this is another class describing integer sequences, and it derives directly as a subclass of *MObject*. It's another dynamic array.

```

⟨ Public interface for mobjects.pas 310 ⟩ +≡
  IntegerListPtr = ↑IntegerList;
  IntegerList = array [0 .. MaxIntegerListSize - 1] of integer;
  PIntSequence = ↑IntSequence;
  IntSequencePtr = PIntSequence;
  IntSequence = object (MObject)
    fList: IntegerListPtr;
    fCount: integer;
    fCapacity: integer;
    constructor Init(aCapacity : integer);
    constructor CopySequence(const aSeq: IntSequence);
    constructor MoveSequence(var aSeq : IntSequence);
    destructor Done; virtual;
    procedure IntListError(Code, Info : integer); virtual;
    procedure SetCapacity(aCapacity : integer); virtual;
    procedure Clear; virtual;
    function Insert(aInt : integer): integer; virtual;
    procedure AddSequence(const aSeq: IntSequence); virtual;
    function IndexOf(aInt : integer): integer; virtual;
    procedure AtDelete(aIndex : integer); virtual;
    function Value(aIndex : integer): integer; virtual;
    procedure AtInsert(aIndex, aInt : integer); virtual;
    procedure AtPut(aIndex, aInt : integer); virtual;
  end ;

```

553. We will need to quicksort lists of integers. This will mutate the *aList* argument, making it sorted. See also §398 and §479.

This procedure does not appear to be used anywhere in Mizar.

(*IntSequence* implementation 553) \equiv

{ integer Sequences & Sets }

```
procedure IntQuickSort(aList : IntegerListPtr; L, R : integer);
var I, J, P, lTemp: integer;
begin repeat I  $\leftarrow$  L; J  $\leftarrow$  R; P  $\leftarrow$  aList $\uparrow$ [(L + R) shr 1];
  repeat while CompareInt(aList $\uparrow$ [I], P) < 0 do inc(I);
    { Invariant: for  $L \leq h < I$ , we have CompareInt(aList $\uparrow$ [h], P) < 0 }
  while CompareInt(aList $\uparrow$ [J], P) > 0 do dec(J);
    { Invariant: for  $J < k \leq R$  we have CompareInt(aList $\uparrow$ [k], P) > 0 }
  if I  $\leq$  J then
    begin lTemp  $\leftarrow$  aList $\uparrow$ [I]; aList $\uparrow$ [I]  $\leftarrow$  aList $\uparrow$ [J]; aList $\uparrow$ [J]  $\leftarrow$  lTemp; inc(I); dec(J);
    end;
    { Invariant: for  $L \leq h \leq I$ , we have CompareInt(aList $\uparrow$ [h], P) < 0 }
    { Invariant: for  $J \leq k \leq R$  we have CompareInt(aList $\uparrow$ [k], P) > 0 }
  until I > J;
  if L < J then IntQuickSort(aList, L, J);
  L  $\leftarrow$  I;
until I  $\geq$  R;
end;
```

This code is used in section 309.

554. Constructor. We can create an empty sequence of integers, with a given capacity.

```
constructor IntSequence.Init(aCapacity : integer);
begin inheritedInit; fList  $\leftarrow$  nil; fCount  $\leftarrow$  0; fCapacity  $\leftarrow$  0; SetCapacity(aCapacity);
end;
```

555. Copy constructor. We can copy an existing sequence by simply creating an empty sequence and inserting everything from *aSeq* into the newly created *IntSequence* object.

```
constructor IntSequence.CopySequence(const aSeq: IntSequence);
begin Init(aSeq.fCapacity); AddSequence(aSeq);
end;
```

556. Move constructor. We can create a new array in heap, and move all the elements from a given sequence over, then free up the given sequence. This just updates *aSeq*'s logical size and capacity parameters, moves pointers around, and assigns *aSeq.fList* \leftarrow **nil**. Nothing is “lost”, but the data is “under new management”.

```
constructor IntSequence.MoveSequence(var aSeq : IntSequence);
begin inheritedInit; fCount  $\leftarrow$  aSeq.fCount; fCapacity  $\leftarrow$  aSeq.fCapacity; fList  $\leftarrow$  aSeq.fList;
  aSeq.fCount  $\leftarrow$  0; aSeq.fCapacity  $\leftarrow$  0; aSeq.fList  $\leftarrow$  nil;
end;
```

557. Destructor. Free the inherited data, set the logical size to zero, then resize the array (to free up the array data).

```
destructor IntSequence.Done;
begin inheritedDone; fCount  $\leftarrow$  0; SetCapacity(0);
end;
```

558. Appending an element. Given a finite sequence of integers (a_0, \dots, a_{n-1}) , we can append a value x to produce the finite sequence (a_0, \dots, a_{n-1}, x) . This will mutate the caller.

```
function IntSequence.Insert(aInt : integer): integer;
  begin if fCount = fCapacity then SetCapacity(fCapacity + GrowLimit(fCapacity));
  fList↑[fCount] ← aInt; Insert ← fCount; inc(fCount);
  end;
```

559. Appending a sequence. This takes a finite sequence (a_0, \dots, a_{n-1}) and another finite sequence (b_0, \dots, b_{m-1}) , then forms a new finite sequence $(a_0, \dots, a_{n-1}, b_0, \dots, b_{m-1})$. It mutates the caller.

```
procedure IntSequence.AddSequence(const aSeq: IntSequence);
  var I, r: integer;
  begin for I ← 0 to aSeq.fCount − 1 do r ← Insert(aSeq.fList↑[I]);
  end;
```

560. Clearing a sequence. Update the caller's logical size to zero, then resize the underlying array to consist of zero elements.

```
procedure IntSequence.Clear;
  begin if fCount ≠ 0 then
    begin fCount ← 0; SetCapacity(0);
    end;
  end;
```

561. Soft delete entry in sequence. Removing the i^{th} entry in the sequence

$$(a_0, \dots, a_{i-1}, a_i, a_{i+1}, \dots, a_{n-1})$$

yields the finite sequence $(a_0, \dots, a_{i-1}, a_{i+1}, \dots, a_{n-1})$. If $i < 0$ or $n - 1 < i$, then we raise an error.

```
procedure IntSequence.AtDelete(aIndex : integer);
  begin if (aIndex < 0) ∨ (aIndex ≥ fCount) then IntListError(coIndexError, aIndex);
  dec(fCount);
  if aIndex < fCount then Move(fList↑[aIndex + 1], fList↑[aIndex], (fCount − aIndex) * SizeOf(integer));
  end;
```

562. We report errors using this helper function.

```
procedure IntSequence.IntListError(Code, Info : integer);
  begin RunError(212 − Code); {! poprawic bledy}
  end;
```

563. Let (a_0, \dots, a_{n-1}) be a finite sequence. The value at index i is a_i when $0 \leq i \leq n - 1$, otherwise it raises an error.

```
function IntSequence.Value(aIndex : integer): integer;
  begin if (aIndex < 0) ∨ (aIndex ≥ fCount) then IntListError(coIndexError, aIndex);
  Value ← fList↑[aIndex];
  end;
```

564. For a finite sequence (a_0, \dots, a_{n-1}) and a value x , if there is some entry $a_i = x$ with $a_j \neq x$ for all $j < i$, then return i . Otherwise return -1 . That is to say, returns the first index of an entry matching the given value (if any), defaults to -1 when there is no entry.

function *IntSequence.IndexOf*(*aInt* : integer): integer;

```

var lResult: integer;
begin for lResult  $\leftarrow$  fCount - 1 downto 0 do
  if fList $\uparrow$ [lResult] = aInt then
    begin IndexOf  $\leftarrow$  lResult; exit
    end;
  IndexOf  $\leftarrow$  -1;
end;
```

565. Given a finite sequence (a_0, \dots, a_{n-1}) , an index i , and a value x :

- (1) If $i < 0$ or i is too big, raise an error.
- (2) If the logical size of the sequence equals its capacity, then grow the underlying array.
- (3) If i is less than the logical size $i < n - 1$, then shift all the entries to the right by 1 so we have $(a_0, \dots, a_{i-1}, 0, a_i, \dots, a_{n-1})$
- (4) Set the i^{th} entry to x , so we end up with the caller becoming $(a_0, \dots, a_{i-1}, x, a_i, \dots, a_{n-1})$.

procedure *IntSequence.AtInsert*(*aIndex*, *aInt* : integer);

```

begin if (aIndex < 0)  $\vee$  (aIndex > fCount) then IntListError(coIndexError, aIndex);
if fCount = fCapacity then SetCapacity(fCapacity + GrowLimit(fCapacity));
if aIndex < fCount then Move(fList $\uparrow$ [aIndex], fList $\uparrow$ [aIndex + 1], (fCount - aIndex) * SizeOf(integer));
fList $\uparrow$ [aIndex]  $\leftarrow$  aInt; inc(fCount);
end;
```

566. Update entry of sequence. For a sequence (a_0, \dots, a_{n-1}) , an index i , and a new value x , if $0 \leq i \leq n - 1$ then we set $a_i \leftarrow x$. Otherwise we have the index be out of bounds ($0 < i$ or $n - 1 < i$), and we should raise an error.

procedure *IntSequence.AtPut*(*aIndex*, *aInt* : integer);

```

begin if (aIndex < 0)  $\vee$  (aIndex  $\geq$  fCount) then IntListError(coIndexError, aIndex);
fList $\uparrow$ [aIndex]  $\leftarrow$  aInt;
end;
```

567. Grow the underlying array. When we want to increase (or decrease) the capacity of the underlying array, we invoke this function. It will copy over the relevant contents.

procedure *IntSequence.SetCapacity*(*aCapacity* : integer);

```

var lList: IntegerListPtr;
begin if aCapacity < fCount then aCapacity  $\leftarrow$  fCount;
if aCapacity > MaxListSize then aCapacity  $\leftarrow$  MaxListSize;
if aCapacity  $\neq$  fCapacity then
  begin if aCapacity = 0 then lList  $\leftarrow$  nil
  else begin GetMem(lList, aCapacity * SizeOf(integer));
    if (fCount  $\neq$  0)  $\wedge$  (fList  $\neq$  nil) then Move(fList $\uparrow$ , lList $\uparrow$ , fCount * SizeOf(integer));
    end;
  if fCapacity  $\neq$  0 then FreeMem(fList, fCapacity * SizeOf(integer));
  fList  $\leftarrow$  lList; fCapacity  $\leftarrow$  aCapacity;
  end;
end;
```

Section 10.20. INTEGER SETS

568. A finite set of integers is represented by a finite sequence of integers which has no duplicate entries. In other words, an injective finite sequence of integers.

⟨Public interface for `mobjects.pas` 310⟩ $\vdash \equiv$

```

PIntSet =  $\uparrow$ IntSet;
IntSetPtr = pIntSet;
IntSet = object (IntSequence)
  function Insert(aInt : integer): integer; virtual;
  function DeleteInt(aInt : integer): integer; virtual;
  function Find(aInt : integer; var aIndex : integer): Boolean; virtual;
  function IndexOf(aInt : integer): integer; virtual;
  procedure AtInsert(aIndex, aInt : integer): virtual;
  function IsInSet(aInt : integer): Boolean; virtual;
  function IsEqualTo(const aSet: IntSet): Boolean; virtual;
  function IsSubsetOf(const aSet: IntSet): Boolean; virtual;
  function IsSupersetOf(var aSet : IntSet): Boolean; virtual;
  function Misses(var aSet : IntSet): Boolean; virtual;
end ;

```

569. Insert an element. When inserting an element x into a set A , we check if $x \in A$ is already a member. If so, then we're done.

Otherwise, we ensure the capacity of the set can handle adding another element. Then we shift all elements greater than x over to the right by 1. We finally insert x into the underlying array.

Ensures the resulting array is sorted, provided it was sorted before this function was called.

⟨*IntSet* Implementation 569⟩ \equiv

```

function IntSet.Insert(aInt : integer): integer;
  var lIndex: integer;
  begin if Find(aInt, lIndex) then { already contains the element? }
    begin Insert  $\leftarrow$  lIndex; exit end;
  if fCount = fCapacity then SetCapacity(fCapacity + GrowLimit(fCapacity));
  if lIndex < fCount then Move(fList $\uparrow$ [lIndex], fList $\uparrow$ [lIndex + 1], (fCount - lIndex) * SizeOf(integer));
  fList $\uparrow$ [lIndex]  $\leftarrow$  aInt; inc(fCount); Insert  $\leftarrow$  lIndex;
  end;

```

This code is used in section 309.

570. Soft delete an element. Removing an element from a set. This will return the former index of the element in the underlying array.

```

function IntSet.DeleteInt(aInt : integer): integer;
  var lIndex: integer;
  begin DeleteInt  $\leftarrow$  -1;
  if Find(aInt, lIndex) then
    begin DeleteInt  $\leftarrow$  lIndex; AtDelete(lIndex) end
  end;

```

571. Finding an element. We can use bisection search to find an element $aInt$ in the underlying array. It will mutate $aIndex$ to be where the entry should be, and return *true* if the element is a member of the set (and *false* otherwise).

```
function IntSet.Find( $aInt$  : integer; var  $aIndex$  : integer): Boolean;
  var  $L, H, I, C$ : integer;
  begin Find  $\leftarrow$  False;  $L \leftarrow 0$ ;  $H \leftarrow fCount - 1$ ;
  while  $L \leq H$  do
    begin  $I \leftarrow (L + H) \text{ shr } 1$ ;  $C \leftarrow CompareInt(fList\uparrow[I], aInt)$ ;
    if  $C < 0$  then  $L \leftarrow I + 1$ 
    else begin  $H \leftarrow I - 1$ ;
    if  $C = 0$  then
      begin Find  $\leftarrow$  True;  $L \leftarrow I$ ; end;
    end;
  end;
   $aIndex \leftarrow L$ ;
end;
```

572. Index of element . We can find the index of an element (if it is present) by using bisection search.

```
function IntSet.IndexOf( $aInt$  : integer): integer;
  var  $lResult$ : integer;
  begin if  $\neg Find(aInt, lResult)$  then  $lResult \leftarrow -1$ ;
  IndexOf  $\leftarrow lResult$ ;
end;
```

573. The *AtInsert* method is “grandfathered in”, but not supported, so we raise an error if anyone tries using it.

```
procedure IntSet.AtInsert( $aIndex, aInt$  : integer);
  begin IntListError(coSortedListError, 0);
end;
```

574. Test for membership. We can test if an integer is an element of the set, again just piggy-backing off bisection search.

```
function IntSet.IsInSet( $aInt$  : integer): Boolean;
  var  $I$ : integer;
  begin IsInSet  $\leftarrow Find(aInt, I)$ ;
end;
```

575. Set equality. Testing if two finite sets A and B of integers are equal requires $|A| = |B|$ and for each $x \in A$ we have $x \in B$. If these conditions are not both met, then $A \neq B$. (This is established by Theorem [CARD.2:102](#).)

```
function IntSet.IsEqualTo(const  $aSet$ : IntSet): Boolean;
  var  $I$ : integer;
  begin IsEqualTo  $\leftarrow$  false;
  if  $fCount \neq aSet.fCount$  then exit;
  for  $I \leftarrow 0$  to  $fCount - 1$  do
    if  $fList\uparrow[I] \neq aSet.fList\uparrow[I]$  then exit;
  IsEqualTo  $\leftarrow$  true;
end;
```

576. Subset predicate. We can test $A \subseteq B$ by $|A| \leq |B|$ and for each $a \in A$ we have $a \in B$. (This is a consequence of Theorem [CARD_2:48](#).)

```

function IntSet.IsSubsetOf(const aSet: IntSet): Boolean;
  var i, j, lnt: integer;
  begin IsSubsetOf  $\leftarrow$  false;
  if aSet.fCount < fCount then exit;
  j  $\leftarrow$  0; { index of B }
  for i  $\leftarrow$  0 to fCount - 1 do { loop over  $a \in A$  }
    begin lnt  $\leftarrow$  fList $\uparrow$ [i];
    while (j < aSet.fCount)  $\wedge$  (aSet.fList $\uparrow$ [j] < lnt) do inc(j);
    if (j = aSet.fCount)  $\vee$  (aSet.fList $\uparrow$ [j]  $\neq$  fList $\uparrow$ [i]) then exit;
    end;
  IsSubsetOf  $\leftarrow$  true;
end;

```

577. Superset predicate. We have $A \supseteq B$ if $B \subseteq A$.

```

function IntSet.IsSupersetOf(var aSet : IntSet): Boolean;
  begin IsSupersetOf  $\leftarrow$  aSet.IsSubsetOf(Self);
end;

```

578. Test for disjointness. We have $A \cap B = \emptyset$ if every $a \in A$ is such that $a \notin B$. There are fewer iterations in the loop if we test every element in the smaller set is not a member of the larger set. This trick works because “misses” is a symmetric predicate.

```

function IntSet.Misses(var aSet : IntSet): Boolean;
  var k: integer;
  begin if fCount > aSet.fCount then
    begin for k  $\leftarrow$  0 to aSet.fCount - 1 do
      if IsInSet(aSet.fList $\uparrow$ [k]) then
        begin Misses  $\leftarrow$  false; exit end
      end
    else begin for k  $\leftarrow$  0 to fCount - 1 do
      if aSet.IsInSet(fList $\uparrow$ [k]) then
        begin Misses  $\leftarrow$  false; exit end;
      end;
    Misses  $\leftarrow$  true;
  end;

```

Section 10.21. PARTIAL BINARY INTEGER FUNCTIONS

579. We want to describe partial functions like $f: \mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$. These are encoded as finite sets of triples $\{(x, y, f(x, y)) \in \mathbf{Z} \times \mathbf{Z} \times \mathbf{Z}\}$. So we need to introduce triples of integers.

We stress the class hierarchy: the parent class is *MObject* itself.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  IntTripletListPtr = ↑IntTripletList;
  IntTripletList = array [0 .. MaxIntTripletSize - 1] of IntTriplet;
  BinIntFuncPtr = ↑BinIntFunc;
  BinIntFunc = object (MObject)
    fList: IntTripletListPtr;
    fCount: integer;
    fCapacity: integer;
    constructor Init(aLimit : integer);
    procedure BinIntFuncError(aCode, aInfo : integer); virtual;
    destructor Done; virtual;

    procedure Insert(const aItem: IntTriplet); virtual;
    procedure AtDelete(aIndex : integer);
    procedure SetCapacity(aLimit : integer); virtual;
    procedure DeleteAll;
    function Search(X1, X2 : integer; var aIndex : integer): Boolean; virtual;
    function IndexOf(X1, X2 : integer): integer;
    constructor CopyBinIntFunc(var aFunc : BinIntFunc);
    function HasInDom(X1, X2 : integer): Boolean; virtual;
    procedure Assign(X1, X2, Y : integer); virtual;
    procedure Up(X1, X2 : integer); virtual;
    procedure Down(X1, X2 : integer); virtual;
    function Value(X1, X2 : integer): integer; virtual;
    procedure Add(const aFunc: BinIntFunc); virtual;
    function CountAll: integer; virtual;
  end ;

```

580. We have a convenience function for reporting errors.

```

⟨Partial Binary integer Functions 580⟩ ≡
procedure BinIntFunc.BinIntFuncError(aCode, aInfo : integer);
  begin RunError(212 - aCode); end;

```

This code is used in section 309.

581. Constructor. We initialize the empty partial function, and create an array whose capacity is initialized to *aLimit*.

```

constructor BinIntFunc.Init(aLimit : integer);
  begin MObject.Init; fList ← nil; fCount ← 0; fCapacity ← 0; SetCapacity(aLimit);
  end;

```

582. Destructor. We assign the logical size of the caller to zero, then resize the underlying array to zero elements (i.e., free everything).

```

destructor BinIntFunc.Done;
  begin fCount ← 0; SetCapacity(0);
  end;

```

583. Insert an entry. If we have a partial function $f: \mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$ and a triple (x_1, x_2, y) , then check if $(x_1, x_2) \in \text{dom}(f)$. If so, we're done — this will not overwrite the value at that argument.

Otherwise we add $f(x_1, x_2) = y$ to the partial function.

```

procedure BinIntFunc.Insert(const aItem: IntTriplet);
  var I: integer;
  begin if  $\neg \text{Search}(aItem.X1, aItem.X2, I)$  then  $\{ (x_1, x_2) \notin \text{dom}(f) \}$ 
    begin if  $(I < 0) \vee (I > fCount)$  then  $\{ \text{index out of bounds} \}$ 
      begin BinIntFuncError(coIndexError, 0); exit; end;
    if  $fCapacity = fCount$  then SetCapacity( $fCapacity + \text{GrowLimit}(fCapacity)$ );
    if  $I \neq fCount$  then Move( $fList \uparrow [I], fList \uparrow [I + 1], (fCount - I) * \text{SizeOf}(\text{IntTriplet})$ );
     $fList \uparrow [I] \leftarrow aItem$ ;  $\text{inc}(fCount)$ ;
  end;
end;

```

584. Delete an entry. Given $f: \mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$, we represent it as an array of $\mathbf{Z} \times \mathbf{Z} \times \mathbf{Z}$. So we can remove the entry at index i when $0 \leq i < \|f\|$. Otherwise when $i < 0$ or $\|f\| \leq i$, raise an error.

```

procedure BinIntFunc.AtDelete(aIndex : integer);
  var i: integer;
  begin if  $(aIndex < 0) \vee (aIndex \geq fCount)$  then
    begin BinIntFuncError(coIndexError, 0); exit; end;
  if  $aIndex < fCount - 1$  then
    for  $i \leftarrow aIndex$  to  $fCount - 2$  do  $fList \uparrow [i] \leftarrow fList \uparrow [i + 1]$ ;
   $\text{dec}(fCount)$ ;
end;

```

585. Ensure capacity. We need to ensure $fCount \leq aLimit \leq \text{MaxIntTripletSize}$, by assigning $aLimit$ to be $fCount$ (when $aLimit < fCount$) or MaxIntTripletSize (when $aLimit$ is bigger).

We allocate a new array (when the new capacity is nonzero) and copy the data over to the new array. Then we delete the old array if it exists (tested by $fCapacity \neq 0$). Then we just update the caller's $fList$ pointer and capacity field.

```

procedure BinIntFunc.SetCapacity(aLimit : integer);
  var aItems: IntTripletListPtr;
  begin  $\{ \text{Ensure } fCount \leq aLimit \leq \text{MaxIntTripletSize} \}$ 
  if  $aLimit < fCount$  then  $aLimit \leftarrow fCount$ ;
  if  $aLimit > \text{MaxIntTripletSize}$  then  $aLimit \leftarrow \text{MaxIntTripletSize}$ ;
  if  $aLimit \neq fCapacity$  then  $\{ \text{allocate a new array, copy data over} \}$ 
    begin if  $aLimit = 0$  then  $aItems \leftarrow \text{nil}$ 
      else begin GetMem( $aItems, aLimit * \text{SizeOf}(\text{IntTriplet})$ );
        if  $(fCount \neq 0) \wedge (fList \neq \text{nil})$  then Move( $fList \uparrow, aItems \uparrow, fCount * \text{SizeOf}(\text{IntTriplet})$ );
      end;
    if  $fCapacity \neq 0$  then FreeMem( $fList, fCapacity * \text{SizeOf}(\text{IntTriplet})$ );
     $fList \leftarrow aItems$ ;  $fCapacity \leftarrow aLimit$ ;
  end;
end;

```

586. Hard delete all entries. Deleting all entries in a partial function $\mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$ amounts to setting the logical size of the underlying dynamic array to zero.

```

procedure BinIntFunc.DeleteAll;
  begin  $fCount \leftarrow 0$ ; end;

```

587. Search for entry. We can use bisection search to find an entry (x_1, x_2) such that $(x_1, x_2) \in \text{dom}(f)$.

```
function BinIntFunc.Search( $X1, X2 : \text{integer}$ ; var  $aIndex : \text{integer}$ ): Boolean;
  var  $L, H, I, C : \text{integer}$ ;
  begin Search  $\leftarrow$  False;  $L \leftarrow 0$ ;  $H \leftarrow fCount - 1$ ;
  while  $L \leq H$  do
    begin  $I \leftarrow (L + H) \text{ shr } 1$ ;  $C \leftarrow \text{CompareIntPairs}(fList\uparrow[I].X1, fList\uparrow[I].X2, X1, X2)$ ;
    if  $C < 0$  then  $L \leftarrow I + 1$ 
    else begin  $H \leftarrow I - 1$ ;
      if  $C = 0$  then
        begin Search  $\leftarrow$  True;  $L \leftarrow I$ ; end;
      end;
    end;
  end;
   $aIndex \leftarrow L$ ;
end;
```

588. Copy constructor. This leaves $aFunc$ unchanged, and clones $aFunc$. Remember *Move* is misnamed because of Borland, it really copies data (despite what the name would lead you to believe).

```
constructor BinIntFunc.CopyBinIntFunc(var  $aFunc : \text{BinIntFunc}$ );
  begin Init( $aFunc.fCapacity$ ); Move( $aFunc.fList\uparrow, fList\uparrow, aFunc.fCapacity * \text{SizeOf}(\text{IntTriplet})$ );
   $fCount \leftarrow aFunc.fCount$ ;
end;
```

589. Index of entry. Given $f: \mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$ and (x_1, x_2) , find the index for the underlying dynamic array i such that it contains $(x_1, x_2, f(x_1, x_2))$. If there is no such entry, $i = -1$ is returned.

```
function BinIntFunc.IndexOf( $X1, X2 : \text{integer}$ ): integer;
  var  $I : \text{integer}$ ;
  begin IndexOf  $\leftarrow -1$ ;
  if Search( $X1, X2, I$ ) then IndexOf  $\leftarrow I$ ;
  end;
```

590. Test if defined on pair. Test if $(x_1, x_2) \in \text{dom}(f)$.

```
function BinIntFunc.HasInDom( $X1, X2 : \text{integer}$ ): Boolean;
  var  $I : \text{integer}$ ;
  begin HasInDom  $\leftarrow$  Search( $X1, X2, I$ );
  end;
```

591. Insert an entry. Given $f: \mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$, and $(x_1, x_2) \in \mathbf{Z} \times \mathbf{Z}$ and $y \in \mathbf{Z}$, try setting $f(x_1, x_2) = y$ provided $(x_1, x_2) \notin \text{dom}(f)$ or if $(x_1, x_2, y) \in f$ already. If $f(x_1, x_2) \neq y$ already exists, then raise an error.

```
procedure BinIntFunc.Assign( $X1, X2, Y : \text{integer}$ );
  var  $lIntTriplet : \text{IntTriplet}$ ;
  begin if HasInDom( $X1, X2$ )  $\wedge$  ( $\text{Value}(X1, X2) \neq Y$ ) then
    begin BinIntFuncError( $\text{coDuplicate}, 0$ ); exit
    end;
   $lIntTriplet.X1 \leftarrow X1$ ;  $lIntTriplet.X2 \leftarrow X2$ ;  $lIntTriplet.Y \leftarrow Y$ ; Insert( $lIntTriplet$ );
end;
```

592. Increment value at argument. Given $f: \mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$ and $(x_1, x_2) \in \mathbf{Z} \times \mathbf{Z}$. If $(x_1, x_2) \in \text{dom}(f)$, then set $f(x_1, x_2) \leftarrow f(x_1, x_2) + 1$. Otherwise set $f(x_1, x_2) \leftarrow 1$.

```

procedure BinIntFunc.Up( $X1, X2 : \text{integer}$ );
  var  $I : \text{integer}$ ;  $\text{UntTriplet} : \text{UntTriplet}$ ;
  begin if Search( $X1, X2, I$ ) then inc( $fList \uparrow [I].Y$ )
  else begin  $\text{UntTriplet}.X1 \leftarrow X1$ ;  $\text{UntTriplet}.X2 \leftarrow X2$ ;  $\text{UntTriplet}.Y \leftarrow 1$ ; Insert( $\text{UntTriplet}$ );
    end;
  end;

```

593. Decrement value at argument. Given $f: \mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$ and $(x_1, x_2) \in \mathbf{Z} \times \mathbf{Z}$. If $(x_1, x_2) \in \text{dom}(f)$, then set $f(x_1, x_2) \leftarrow f(x_1, x_2) - 1$. Further, if $f(x_1, x_2) = 0$, then remove it from the underlying dynamic array.

Otherwise for $(x_1, x_2) \notin \text{dom}(f)$, raise an error.

```

procedure BinIntFunc.Down( $X1, X2 : \text{integer}$ );
  var  $I : \text{integer}$ ;
  begin if Search( $X1, X2, I$ ) then
    begin dec( $fList \uparrow [I].Y$ );
    if  $fList \uparrow [I].Y = 0$  then AtDelete( $I$ );
    end
  else BinIntFuncError(coConsistentError, 0);
  end;

```

594. Return value for argument. Given $f: \mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$, and $(x_1, x_2) \in \mathbf{Z} \times \mathbf{Z}$, if $(x_1, x_2) \notin \text{dom}(f)$ then raise an error. Otherwise when $(x_1, x_2) \in \text{dom}(f)$, return $f(x_1, x_2)$.

```

function BinIntFunc.Value( $X1, X2 : \text{integer}$ ): integer;
  var  $I : \text{integer}$ ;
  begin if Search( $X1, X2, I$ ) then  $\text{Value} \leftarrow fList \uparrow [I].Y$ 
  else BinIntFuncError(coDuplicate, 0);
  end;

```

595. Add two partial functions together. Given two partial functions $f, g: \mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$, compute $f + g: \mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$. This is defines by:

- (1) For $(x_1, x_2) \in \text{dom}(f) \cap \text{dom}(g)$, set $(f + g)(x_1, x_2) = f(x_1, x_2) + g(x_1, x_2)$
- (2) For $(x_1, x_2) \in \text{dom}(f) \setminus \text{dom}(g)$, set $(f + g)(x_1, x_2) = f(x_1, x_2)$
- (3) For $(x_1, x_2) \in \text{dom}(g) \setminus \text{dom}(f)$, set $(f + g)(x_1, x_2) = g(x_1, x_2)$.

{ **TODO:** this is inefficient, since the search is repeated in the *Assign* method; fix this both here and in other similar methods }

```

procedure BinIntFunc.Add(const  $aFunc : \text{BinIntFunc}$ );
  var  $k, l : \text{integer}$ ;
  begin for  $k \leftarrow 0$  to  $aFunc.fCount - 1$  do
    if Search( $aFunc.fList \uparrow [k].X1, aFunc.fList \uparrow [k].X2, l$ ) then inc( $fList \uparrow [l].Y, aFunc.fList \uparrow [k].Y$ )
    else Assign( $aFunc.fList \uparrow [k].X1, aFunc.fList \uparrow [k].X2, aFunc.fList \uparrow [k].Y$ );
  end;

```

596. Sum all values. For $f: \mathbf{Z} \times \mathbf{Z} \rightarrow \mathbf{Z}$, we compute

$$\text{CountAll}(f) = \sum_{(m,n) \in \text{dom}(f)} f(m,n).$$

```

function BinIntFunc.CountAll: integer;
  var k, l: integer;
  begin l  $\leftarrow$  0;
  for k  $\leftarrow$  0 to fCount - 1 do inc(l, fList↑[k].Y);
  CountAll  $\leftarrow$  l;
  end;

```

Section 10.22. PARTIAL INTEGERS TO PAIR OF INTEGERS FUNCTIONS

597. Partial functions of the form $f: \mathbf{Z} \rightarrow \mathbf{Z} \times \mathbf{Z}$. Note the class hierarchy: this is a direct subclass of *MObject*. This is used only in the `first_identification.pas` file.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  Int2PairOfInt = record X, Y1, Y2: integer;
    end;
  Int2PairOfIntFuncPtr = ↑Int2PairOfIntFunc;
  Int2PairOfIntFunc = object (MObject)
    fList: array of Int2PairOfInt;
    fCount: integer;
    fCapacity: integer;
    constructor Init(aLimit : integer);
    procedure Int2PairOfIntFuncError(aCode, aInfo : integer); virtual;
    destructor Done; virtual;

    procedure Insert(const aItem: Int2PairOfInt); virtual;
    procedure AtDelete(aIndex : integer);
    procedure SetCapacity(aLimit : integer); virtual;
    procedure DeleteAll;
    function Search(X : integer; var aIndex : integer): Boolean; virtual;
    function IndexOf(X : integer): integer;
    constructor CopyInt2PairOfIntFunc(var aFunc : Int2PairOfIntFunc);
    function HasInDom(X : integer): Boolean; virtual;
    procedure Assign(X, Y1, Y2 : integer); virtual;
    function Value(X : integer): IntPair; virtual;
  end ;

```

598. We have a helper function for raising errors.

```

⟨Partial integers to Pair of integers Functions 598⟩ ≡
  { Partial integers to Pair of integers Functions }
  procedure Int2PairOfIntFunc.Int2PairOfIntFuncError(aCode, aInfo : integer);
  begin RunError(212 - aCode);
  end;

```

This code is used in section 309.

599. Constructor. Creates an empty $f: \mathbf{Z} \rightarrow \mathbf{Z} \times \mathbf{Z}$ with an underlying dynamic array whose capacity is given as the argument *aLimit*.

```

constructor Int2PairOfIntFunc.Init(aLimit : integer);
begin MObject.Init; fList ← nil; fCount ← 0; fCapacity ← 0; SetCapacity(aLimit);
end;

```

600. Destructor. We set the logical size to zero, then ensure the capacity of the underlying array is zero (thereby hard deleting the array).

```

destructor Int2PairOfIntFunc.Done;
begin fCount ← 0; SetCapacity(0);
end;

```

601. Insert an entry. Inserting (x, y_1, y_2) into $f: \mathbf{Z} \rightarrow \mathbf{Z} \times \mathbf{Z}$ amounts to checking if $(x, y_1, y_2) \in f$. If not, then insert the entry.

Otherwise, if $(x, y_1, y_2) \notin f$ but $x \in \text{dom}(f)$, then raise an error.

Otherwise do nothing.

```

procedure Int2PairOfIntFunc.Insert(const aItem: Int2PairOfInt);
  var I: integer;
  begin if  $\neg \text{Search}(aItem.X, I)$  then
    begin if  $(I < 0) \vee (I > fCount)$  then
      begin Int2PairOfIntFuncError(coIndexError, 0); exit; end;
    if  $fCapacity = fCount$  then SetCapacity( $fCapacity + \text{GrowLimit}(fCapacity)$ );
    if  $I \neq fCount$  then Move(fList[I], fList[I + 1],  $(fCount - I) * \text{SizeOf}(\text{Int2PairOfInt})$ );
    fList[I]  $\leftarrow$  aItem; inc(fCount);
    end
  else if  $(fList[I].Y1 \neq aItem.Y1) \vee (fList[I].Y2 \neq aItem.Y2)$  then
    begin Int2PairOfIntFuncError(coDuplicate, 0); exit; end;
  end;

```

602. Hard delete an entry. Delete an entry from the underlying dynamic array. Raise an error if the index given is out of bounds.

```

procedure Int2PairOfIntFunc.AtDelete(aIndex : integer);
  var i: integer;
  begin if  $(aIndex < 0) \vee (aIndex \geq fCount)$  then { index out of bounds }
    begin Int2PairOfIntFuncError(coIndexError, 0); exit;
    end;
  if  $aIndex < fCount - 1$  then
    for  $i \leftarrow aIndex$  to  $fCount - 2$  do fList[i]  $\leftarrow$  fList[i + 1];
  dec(fCount);
  end;

```

603. Ensure capacity. There is no test that *aLimit* is less than some maximum size, unlike every other similar “ensure capacity” function in this file. And we use the built-in *SetLength* primitive function from PASCAL to resize the dynamic array.

```

procedure Int2PairOfIntFunc.SetCapacity(aLimit : integer);
  begin if  $aLimit < fCount$  then  $aLimit \leftarrow fCount$ ;
  setlength(fList, aLimit);  $fCapacity \leftarrow aLimit$ ;
  end;

```

604. Soft delete all entries. We can “soft delete” all entries in the partial function.

```

procedure Int2PairOfIntFunc.DeleteAll;
  begin  $fCount \leftarrow 0$ ;
  end;

```

605. Search for entry. We can bisection search on the domain. Observe: once the needle has been found in the haystack, we have $H \leftarrow I - 1$ and $L \leftarrow I$, which means the loop will terminate.

```

function Int2PairOfIntFunc.Search( $X : integer$ ; var  $aIndex : integer$ ): Boolean;
  var  $L, H, I, C : integer$ ;
  begin  $Search \leftarrow False$ ;  $L \leftarrow 0$ ;  $H \leftarrow fCount - 1$ ;
  while  $L \leq H$  do
    begin  $I \leftarrow (L + H) \text{ shr } 1$ ;  $C \leftarrow CompareInt(fList[I].X, X)$ ;
    if  $C < 0$  then  $L \leftarrow I + 1$ 
    else begin  $H \leftarrow I - 1$ ;
      if  $C = 0$  then
        begin  $Search \leftarrow True$ ;  $L \leftarrow I$ ;
        end;
      end;
    end;
  end;
   $aIndex \leftarrow L$ ;
end;

```

606. Copy constructor. This leaves the argument $aFunc$ unchanged. [[The argument should be a **const** not a **var** ?]]

```

constructor Int2PairOfIntFunc.CopyInt2PairOfIntFunc(var  $aFunc : Int2PairOfIntFunc$ );
  begin  $Init(aFunc.fCapacity)$ ;  $Move(aFunc.fList[0], fList[0], aFunc.fCapacity * SizeOf(Int2PairOfInt))$ ;
   $fCount \leftarrow aFunc.fCount$ ;
end;

```

607. Index of argument. Find the index in the underlying dynamic array for $x \in \text{dom}(f)$. If $x \notin \text{dom}(f)$, then return -1 .

```

function Int2PairOfIntFunc.IndexOf( $X : integer$ ): integer;
  var  $I : integer$ ;
  begin  $IndexOf \leftarrow -1$ ;
  if  $Search(X, I)$  then  $IndexOf \leftarrow I$ ;
end;

```

608. Test if defined at point. Test if $x \in \text{dom}(f)$.

```

function Int2PairOfIntFunc.HasInDom( $X : integer$ ): Boolean;
  var  $I : integer$ ;
  begin  $HasInDom \leftarrow Search(X, I)$ ;
end;

```

609. Assign an entry. Attempt to insert (x, y_1, y_2) into $f: \mathbf{Z} \rightarrow \mathbf{Z} \times \mathbf{Z}$. This will not overwrite a pre-existing entry, as per the contract of *Int2PairOfIntFunc.Insert* (§601).

```

procedure Int2PairOfIntFunc.Assign( $X, Y1, Y2 : integer$ );
  var  $lInt2PairOfInt : Int2PairOfInt$ ;
  begin  $lInt2PairOfInt.X \leftarrow X$ ;  $lInt2PairOfInt.Y1 \leftarrow Y1$ ;  $lInt2PairOfInt.Y2 \leftarrow Y2$ ;
   $Insert(lInt2PairOfInt)$ ;
end;

```

610. Determine value at argument. Given $f: \mathbf{Z} \rightarrow \mathbf{Z} \times \mathbf{Z}$ and $x \in \mathbf{Z}$, if $x \in \text{dom}(f)$ return $f(x)$. Otherwise raise an error.

```

function Int2PairOfIntFunc.Value(X : integer): IntPair;
  var I: integer;
  begin if Search(X, I) then
    begin Result.X  $\leftarrow$  fList[I].Y1; Result.Y  $\leftarrow$  fList[I].Y2;
    end
  else Int2PairOfIntFuncError(coDuplicate, 0);
  end;

```

611. Lingering random declarations in the interface. We have a myriad of random declarations, so we just stick them all here.

```

⟨Public interface for mobjects.pas 310⟩ +≡
  { Comparing Strings wrt MStrObj }
function CompareStringPtr(aKey1, aKey2 : Pointer): integer;
  { Comparing Strings and integers }
function CompareStr(aStr1, aStr2 : string): integer;
function CompareIntPairs(X1, Y1, X2, Y2 : Longint): integer;
  { Dynamic String handling routines }
function NewStr(const S: string): PString;
procedure DisposeStr(P : PString);
function GrowLimit(aLimit : integer): integer;    { Abstract notification procedure }
function CompareNatFunc(aKey1, aKey2 : Pointer): integer;
procedure Abstract1;
var EmptyNatFunc: NatFunc;

File 12

Environment library

617. We have a library to handle accessing the Mizar mathematical library files. This is used in `ma-keenv.dpr` and using local `./pre1/` directories.

This will execute *InitLibrEnv* (§643) and *CheckCompatibility* (§639).

Here the assumption that there's an environment variable “\$MIZFILES” set to the directory containing the Mizar Mathematical library. We discussed environment variables earlier (§65).

```

<base/librenv.pas 617> ≡
  <GNU License 4>
unit librenv;
interface
  uses mobjects;
  const MML = 'mml'; EnvMizFiles = 'MIZFILES';
  <Public function declarations for librenv.pas 627>
  type <Declare FileDescr data type 619>
    <Declare FileDescrCollection data type 622>
  var <Global variables declared in librenv.pas 618>
implementation
  uses
    if_def (WIN32) windows, end_if
    mizenv, pcmizver, mconsole;
  <Implementation for librenv.pas 620>
  begin InitLibrEnv; CheckCompatibility;
end.

```

618. <Global variables declared in librenv.pas 618> ≡
MizPath: *string*; { path to where Mizar binaries are located }
MizFiles: *string*; { the “\$MIZFILES” environment variable }
LocFilesCollection: *FileDescrCollection*;

This code is used in section 617.

Section 12.1. FILE DESCRIPTORS

619. We use file descriptors for things. These are just “a file name” and “a timestamp”. The “file name” is either an absolute path to a file in the Mizar mathematical library, or a relative path to a file in the user’s local “./pre1/” subdirectory.

Historically, the notion of “file descriptors” pre-dates UNIX. For example, R.F. Clippinger’s “FACT—A Business Compiler: Description and Comparison with COBOL and Commercial Translator” (*Int. Tracts Comput. Sci. Technol. Their Appl.* **2** (1961) 231–292, [doi:10.1016/B978-1-4831-9779-1.50014-8](https://doi.org/10.1016/B978-1-4831-9779-1.50014-8)) seems to be among the earliest use of the term.

CAUTION: PASCAL’s *LongInt* is a 32-bit signed integer, which means that Mizar will experience the 2038 “Y2k” bug on 03:14:07 UTC on 19 January 2038. Switching to *Int64* would solve this problem (well, delay it for a time longer than the lifetime of the universe).

```

⟨Declare FileDescr data type 619⟩ ≡
  PFileDescr = ↑FileDescr;
  FileDescr = object (MObject)
    nName: PString;
    Time: LongInt;
    constructor Init (fIdent : string; fTime : LongInt);
    destructor Done; virtual;
  end ;

```

This code is used in section 617.

620. Constructor. When creating a new *FileDescr* object, we should allocate enough space for a copy of the file name. The object then “owns” this copy of the file name string, and must free it when the object is freed from memory.

```

⟨Implementation for librenv.pas 620⟩ ≡
constructor FileDescr.Init (fIdent : string; fTime : LongInt);
  begin nName ← NewStr(fIdent); Time ← fTime;
  end;

```

See also sections 623, 628, 630, 632, 634, 638, 639, and 643.

This code is used in section 617.

621. Destructor. We need to free the string “owned” by the file descriptor object.

```

destructor FileDescr.Done;
  begin DisposeStr(nName);
  end;

```

Section 12.2. COLLECTION OF FILE DESCRIPTIONS

622. This is just *MSortedCollection* (§428) of *FileDescr* objects.

```

⟨ Declare FileDescrCollection data type 622 ⟩ ≡
  PFileDescrCollection = ↑FileDescrCollection;
  FileDescrCollection = object (MSortedCollection)
    function Compare(Key1, Key2 : Pointer): integer; virtual;
    procedure StoreFIL(fName : string);
    constructor LoadFIL(fName : string);
    procedure InsertTimes;
  end ;

```

This code is used in section 617.

623. Ordering file descriptors. Comparing two entries in a file descriptor collection amounts to comparing the names for the file descriptors. [[This should be the *CompareStringPtr* (§424) function, just to keep the code DRY.]]

```

⟨ Implementation for librenv.pas 620 ⟩ +≡
function FileDescrCollection.Compare(Key1, Key2 : Pointer): integer;
  begin if PFileDescr(Key1)↑.nName↑ < PFileDescr(Key2)↑.nName↑ then Compare ← -1
  else if PFileDescr(Key1)↑.nName↑ = PFileDescr(Key2)↑.nName↑ then Compare ← 0
  else Compare ← 1;
  end;

```

624. Populate time field. Inserting file’s “last modified” timestamp into the file descriptors relies upon *mizenv.pas*’s *GetFileTime* (§51) function.

```

procedure FileDescrCollection.InsertTimes;
  var z: integer;
  begin for z ← 0 to Count - 1 do
    with PFileDescr(Items↑[z])↑ do Time ← GetFileTime(nName↑);
  end;

```

625. Constructor. This leverages a few primitive PASCAL functions: *assign(file, name)* assigns *name* to a file but does not open the file (it is still considered closed). Then *reset(file)* opens the file for reading.

Specifically, this will load a *.fil* file produced by Mizar. These contain $2N$ lines: a file path on line $2n-1$, then a timestamp on line $2n$ for $n = 1, \dots, N$. This appears to be used for local *pre1/* files.

```

constructor FileDescrCollection.LoadFIL(fName : string);
  var FIL: text; lName: string; lTime: longint;
  begin Assign(FIL, fName); Reset(FIL); Init(0, 10);
  while ¬eof(FIL) do
    begin ReadLn(FIL, lName); ReadLn(FIL, lTime); Insert(new(PFileDescr, Init(lName, lTime)));
    end;
  close(FIL);
  end;

```

626. Repopulate .fil file. This will erase the file named $fName$, then assign to FIL that file, and $rewrite(FIL)$ will open it for writing.

This will loop through every item in the caller's underlying collection, writing the file names and times to the .fil file.

```
procedure FileDescrCollection.StoreFIL( $fName$  : string);
  var  $FIL$ : text;  $i$ : integer;
  begin EraseFile( $fName$ ); Assign( $FIL$ ,  $fName$ ); Rewrite( $FIL$ ); InsertTimes;
  for  $i \leftarrow 0$  to Count - 1 do
    with PFileDescr(Items↑[ $i$ ]↑) do
      begin WriteLn( $FIL$ ,  $nName$ ↑); WriteLn( $FIL$ , Time)
      end;
  Close( $FIL$ );
end;
```

627. The library path tries to use the local version of a file, if it exists as tested with $MFileExists$ (§47). Otherwise it looks at the Mizar MML version of a file, if it exists.

This returns the path to the file, as a string. If the file cannot be found either in the local prel directory or the MML prel directory, then it returns the empty string.

⟨Public function declarations for `librenv.pas` 627⟩ ≡

```
function LibraryPath( $fName$ ,  $fExt$  : string): string;
```

See also sections 629, 631, 633, and 637.

This code is used in section 617.

628. ⟨Implementation for `librenv.pas` 620⟩ +≡

```
function LibraryPath( $fName$ ,  $fExt$  : string): string;
  begin LibraryPath ← ``;
  if MFileExists(`prel` + DirSeparator +  $fName$  +  $fExt$ ) then { populate with local file }
    begin LocFilesCollection.Insert(New(PFileDescr, Init(`prel` + DirSeparator +  $fName$  +  $fExt$ , 0)));
    LibraryPath ← `prel` + DirSeparator +  $fName$  +  $fExt$ ; exit
    end;
  if MFileExists(MizFiles + `prel` + DirSeparator +  $fName$ [1] + DirSeparator +  $fName$  +  $fExt$ ) then
    LibraryPath ← MizFiles + `prel` + DirSeparator +  $fName$ [1] + DirSeparator +  $fName$  +  $fExt$ ;
  end;
```

629. This function actually is not used anywhere, so I am not sure why we have it.

⟨Public function declarations for `librenv.pas` 627⟩ +≡

```
procedure ReadSortedNames( $fName$  : string; var  $fList$  : MStringCollection); { UNUSED! }
```

630. ⟨Implementation for `librenv.pas` 620⟩ +≡

```
procedure ReadSortedNames( $fName$  : string; var  $fList$  : MStringCollection); { UNUSED! }
  var NamesFile: text;
  begin if  $fName$ [1] = `@` then
    begin Delete( $fName$ , 1, 1); FileExam( $fName$ ); Assign(NamesFile,  $fName$ ); Reset(NamesFile);
     $fList$ .Init(100, 100);
    while ¬seekEof(NamesFile) do
      begin ReadLn(NamesFile,  $fName$ );  $fList$ .Insert(NewStr( $fName$ ));
      end;
    exit;
  end;
   $fList$ .Init(2, 10);  $fList$ .Insert(NewStr( $fName$ ));
end;
```

631. Again, this function is not used anywhere, so I am not sure why we have it.

⟨Public function declarations for `librenv.pas` 627⟩ +≡

```
procedure ReadNames(fName : string; var fList : StringColl); {UNUSED!}
```

632. ⟨Implementation for `librenv.pas` 620⟩ +≡

```
procedure ReadNames(fName : string; var fList : StringColl); {UNUSED!}
  var NamesFile: text;
  begin if fName[1] = '@' then
    begin Delete(fName, 1, 1); FileExam(fName); Assign(NamesFile, fName); Reset(NamesFile);
    fList.Init(10, 10);
    while ¬seekEof(NamesFile) do
      begin ReadLn(NamesFile, fName); fList.Insert(NewStr(fName));
      end;
    exit;
  end;
  fList.Init(2, 10); fList.Insert(NewStr(fName));
end;
```

633. This function is used in `usrtools/lisvoc.dpr`. The *fList* is the *VocList* which consists of all the entries in “\$MIZFILES/mm1.vct”. The *fParam* is either 1 or 2.

If the user writes in a file “foobar” one vocabulary on a line (e.g., “GROUP_1” on one line, “CAT_1” on another), then *fName* ← “@foobar” will lookup the contents “foobar” and load them into the *fList* parameter.

⟨Public function declarations for `librenv.pas` 627⟩ +≡

```
procedure GetSortedNames(fParam : byte; var fList : MStringCollection);
```

634. ⟨Implementation for `librenv.pas` 620⟩ +≡

```
procedure GetSortedNames(fParam : byte; var fList : MStringCollection);
  var FileName: string; NamesFile: text; i: integer;
  begin if ParamCount < fParam then
    begin fList.Init(0, 0); exit
    end;
  FileName ← ParamStr(fParam);
  if FileName[1] = '@' then ⟨Populate fList with the contents of FileName and exit 635⟩;
  ⟨Populate fList with the command-line arguments 636⟩;
end;
```

635. ⟨Populate *fList* with the contents of *FileName* and exit 635⟩ ≡

```
begin Delete(FileName, 1, 1); FileExam(FileName); Assign(NamesFile, FileName);
Reset(NamesFile); fList.Init(10, 10);
while ¬seekEof(NamesFile) do
  begin ReadLn(NamesFile, FileName); fList.Insert(NewStr(TrimString(FileName)));
  end;
exit;
end
```

This code is used in sections 634 and 638.

636. \langle Populate *fList* with the command-line arguments 636 $\rangle \equiv$
fList.Init(2, 8); *fList.Insert*(*NewStr*(*FileName*));
for *i* \leftarrow *fParam* + 1 **to** *ParamCount* **do**
 begin *FileName* \leftarrow *ParamStr*(*i*); *fList.Insert*(*NewStr*(*FileName*));
 end

This code is used in sections 634 and 638.

637. Continuing with the “this is not used anywhere” theme, this function is not used anywhere. The *GetNames* procedure turns out to be the same as *GetSortedNames*.

\langle Public function declarations for *librenv.pas* 627 $\rangle + \equiv$
procedure *GetNames*(*fParam* : byte; **var** *fList* : *StringColl*); { DUPLICATE CODE }

638. \langle Implementation for *librenv.pas* 620 $\rangle + \equiv$
procedure *GetNames*(*fParam* : byte; **var** *fList* : *StringColl*); { DUPLICATE CODE }
 var *FileName*: string; *NamesFile*: text; *i*: integer;
 begin if *ParamCount* < *fParam* **then**
 begin *fList.Init*(0, 0); *exit*
 end;
 FileName \leftarrow *ParamStr*(*fParam*);
 if *FileName*[1] = ‘@’ **then** \langle Populate *fList* with the contents of *FileName* and *exit* 635 \rangle ;
 \langle Populate *fList* with the command-line arguments 636 \rangle ;
 end;

Section 12.3. CHECK COMPATIBILITY OF MIZAR WITH MML

639. We will load the `mml.ini` file for the MML version number, and we check it against the Mizar version. If they are not compatible, print a message to the screen, and halt as an error has occurred.

The `mml.ini` file looks something like:

```
[Mizar verifier]
MizarReleaseNbr=8
MizarVersionNbr=1
MizarVariantNbr=15
[MML]
NumberOfArticles=1493
MMLVersion=5.94
```

We will read line-by-line the `mml.ini` file to initialize several variables. This motivates the *Try_read_ini_var* macro.

[[We should probably move towards TOML rather than INI as the format for storing information, since INI has no standard or specification but TOML has one.]]

```
define init_val_and_end(#) ≡ val(lLine, #, lCode);
end
define Try_read_ini_var(#) ≡ lPos ← Pos(#, lLine);
if lPos > 0 then
begin delete(lLine, 1, lPos + 15); init_val_and_end
```

⟨Implementation for `librenv.pas` 620⟩ +≡

```
procedure CheckCompatibility;
var lFile: text; lLine, lVer1, lVer2, l: string; lPos, lCode: integer;
    lMizarReleaseNbr, lMizarVersionNbr, lMizarVariantNbr: integer;
begin ⟨Open mml.ini file 640⟩
    lMizarReleaseNbr ← -1; lMizarVersionNbr ← -1; lMizarVariantNbr ← -1;
    ⟨Try to read the Mizar version from mml.ini 641⟩;
    close(lFile);
    ⟨Assert MML version is compatible with Mizar version 642⟩
end;
```

640. We open the `$MIZFILES/mml.ini` file for reading.

```
⟨Open mml.ini file 640⟩ ≡
FileExam(MizFiles + MML + '.ini'); Assign(lFile, MizFiles + MML + '.ini'); Reset(lFile);
```

This code is used in section 639.

641. ⟨Try to read the Mizar version from `mml.ini` 641⟩ ≡

```
while ¬seekEof(lFile) do
begin ReadLn(lFile, lLine); Try_read_ini_var('MizarReleaseNbr=')(lMizarReleaseNbr);
    Try_read_ini_var('MizarVersionNbr=')(lMizarVersionNbr);
    Try_read_ini_var('MizarVariantNbr=')(lMizarVariantNbr);
end
```

This code is used in section 639.

642. We need to check the MML version is compatible with the Mizar version. If they are not compatible, raise an error, print a warning to the user, and halt here.

```

⟨ Assert MML version is compatible with Mizar version 642 ⟩ ≡
  if ¬((lMizarReleaseNbr = PCMizarReleaseNbr) ∧ (lMizarVersionNbr = PCMizarVersionNbr)) then
    begin Str(PCMizarReleaseNbr, l); lVer1 ← l; Str(PCMizarVersionNbr, l); lVer1 ← lVer1 + `.` + l;
      Str(PCMizarVariantNbr, l); lVer1 ← lVer1 + `.` + l; Str(lMizarReleaseNbr, l); lVer2 ← l;
      Str(lMizarVersionNbr, l); lVer2 ← lVer2 + `.` + l;
      Str(lMizarVariantNbr, l); lVer2 ← lVer2 + `.` + l; DrawMessage(`Mizar_System_ver.␣` + lVer1 +
        `␣is␣incompatible␣with␣the␣MML␣version␣imported␣` + lVer2 + `)` ,
        `Please␣check␣` + MizFiles + `mml.ini`); halt(1);
    end;

```

This code is used in section 639.

643. Initialize library environment. This will try to initialize the *MizFiles* variable to be equal to the \$MIZFILES environment variable (if that environment variable exists) or the directory of the program being executed. This *MizFiles* will always end in a directory separator.

We also initialize *MizFileName*, *EnvFileName*, *ArticleName*, *ArticleExt* to be empty strings.

```

define append_dir_separator(#) ≡ if #[length(#)] ≠ DirSeparator then # ← # + DirSeparator;
⟨ Implementation for librenv.pas 620 ⟩ +=
procedure InitLibrEnv;
  begin LocFilesCollection.Init(0, 20); MizPath ← ExtractFileDir(ParamStr(0));
  ⟨ Initialize MizFiles 644 ⟩
  MizFileName ← ``; EnvFileName ← ``; ArticleName ← ``; ArticleExt ← ``;
  end;

```

644. Initializing *MizFiles* requires a bit of work. We first guess it based on environment variables. Then we need to ensure it is a directory path.

```

⟨ Initialize MizFiles 644 ⟩ ≡
  ⟨ Guess MizFiles from environment variables or executable path 645 ⟩
  if MizFiles ≠ `` then append_dir_separator(MizFiles);
  if MizFiles = `` then MizFiles ← DirSeparator;

```

This code is used in section 643.

645. When the \$MIZFILES environment variable is set, we just use it. When it is empty or missing, then we guess the path of the executable invoked.

```

⟨ Guess MizFiles from environment variables or executable path 645 ⟩ ≡
  MizFiles ← GetEnvStr(EnvMizFiles);
  if MizFiles = `` then MizFiles ← MizPath;

```

This code is used in section 644.

File 13

XML Parser

646. The XML parser module is used for extracting information from XML files. It does not “validate” the XML (it’s assumed to already be valid). The scanner chops up the input stream into tokens, then the parser makes this available as tokens for the user.

Just to review some terminology from XML:

- (1) A “**tag**” is a markup construct that begins with a “<” and ends with a “>”. There are three types of tags:
 - (i) Start-tags: like “<foo>”
 - (ii) End-tags: like “</foo>”
 - (iii) Empty-element tags: like “
”
- (2) A “**Element**” is a logical document component that either (a) begins with a start-tag and ends with an end-tag, or (b) consists of an empty-element tag. The characters between the start-tag and end-tag (if any) are called its “**Contents**”, and may contain markup including other elements which are called “**Child Elements**”.
- (3) An “**Attribute**” is a markup construct consisting of a name-value pair which can exist in a start-tag or an empty-element tag. For example “” has two attributes: one named “src” whose value is “madonna.jpg”, and the other named “alt” whose value is “Madonna”.
- (4) XML documents may start with an “**XML declaration**” which looks something like (after some optional whitespace) “<?xml version=“1.0” encoding=“UTF-8”?>”

⟨base/xml_parser.pas 646⟩ ≡

⟨GNU License 4⟩

unit *xml_parser*;

interface *uses* *mobjects*, *errhan*;

⟨Type declarations for *xml_parser.pas* 648⟩

procedure *XMLASSERT*(*aCond* : *Boolean*);

procedure *UnexpectedXMLElem*(**const** *aElem*: *string* ; *aErr*: *integer*);

implementation

mdebug *uses info* **end_mdebug**;

⟨Implementation of XML Parser 650⟩

end .

647. Constant parameters. We have a few constant parameters for the error codes.

⟨Constants for *xml_parser.pas* 647⟩ ≡

const *InOutFileBuffSize* = \$4000;

{ for xml attribute tables }

const *errElRedundant* = 7500; { End of element expected, but child element found }

const *errElMissing* = 7501; { Child element expected, but end of element found }

const *errMissingXMLAttribute* = 7502; { Required XML attribute not found }

const *errWrongXMLElement* = 7503; { Different XML element expected }

const *errBadXMLToken* = 7506; { Unexpected XML token }

This code is used in section 646.

648. Public type declarations. We will defer the “PASCAL classes” until we start implementing them. Right now, we have syntactic classes for the tokens. Specifically we have the start of an XML declaration “<?”, the end of an XML declaration “>”, the start of a character data section “<!” , the start and end of tags, quotation marks, equalities, entities, identifiers, and end of text.

```

⟨Type declarations for xml_parser.pas 648⟩ ≡
type XMLTokenKind = (Err, { an error symbol }
  BI, { <? }
  EI, { ?> }
  DT, { <! }
  LT, { < }
  GT, { > }
  ET, { </ }
  EE, { /> }
  QT, { " }
  EQ, { = }
  EN, { Entity }
  ID, { Identifier, Name }
  EOTX); { End of text }
TokensSet = set of XMLTokenKind;
⟨Declare XML Scanner Object type 653⟩
TElementState = (eStart, eEnd); { high-level parser states, see procedure NextElementState }
⟨Declare XML Attribute Object 649⟩
⟨Declare XML Parser object 661⟩

```

This code is used in section 646.

649. XML Attribute Object. An XML attribute contains the attribute name and its value. We can represent it as “just” an *MStrObj* (§317) with an additional “value” field.

```

⟨Declare XML Attribute Object 649⟩ ≡
  XMLAttrPtr = ↑XMLAttrObj;
  XMLAttrObj = object (MStrObj)
    nValue: string;
    constructor Init(const aName, aValue: string);
  end ;

```

This code is used in section 648.

650. Constructor. This uses the *MStrObj.Init* constructor to initialize the name, then it sets the value.

```

⟨Implementation of XML Parser 650⟩ +≡
constructor XMLAttrObj.Init(const aName, aValue: string);
  begin inheritedInit(aName); nValue ← aValue;
  end;

```

See also sections 651, 652, 654, 656, 657, 660, 662, 668, 670, and 671.

This code is used in section 646.

651. Assertion. We have a helper function for asserting things about XML. This is just a wrapper around *MizAssert* (§147).

```

⟨Implementation of XML Parser 650⟩ +≡
procedure XMLASSERT(aCond : Boolean);
  begin MizAssert(errWrongXMLElement, aCond);
  end;

```

652. Unexpected XML Element. Another helper function for checking XML parsing.

⟨Implementation of XML Parser 650⟩ +≡

```
procedure UnexpectedXMLElem(const aElem: string ; aErr: integer);  
  mdebug  
  var lEl: string;  
  end_mdebug  
  begin  
  mdebug InfoNewLine; end_mdebug  
  RunTimeError(aErr);  
  end;
```

Section 13.1. XML SCANNER OBJECT

653. The scanner produces a stream of tokens, which is then consumed by the XML parser. Hence, besides the constructor and destructor, there is only one public facing method: get the next token.

```

⟨ Declare XML Scanner Object type 653 ⟩ ≡
  XMLScannObj = object (MObject)
    nSourceFile: text;
    nSourceFileBuff: pointer;
    nCurTokenKind: XMLTokenKind;
    nSpelling: string;
    nPos: Position;
    nCurCol: integer;
    nLine: string;
    constructor InitScanning(const aFileName: string);
    destructor Done; virtual;
    procedure GetToken; private
    procedure GetAttrValue;
  end ;

```

This code is used in section 648.

654. Constructor. We open the file (doing all the boilerplate file IO stuff), then initialize the fields of the scanner to prepare to read the first line from the file.

```

⟨ Implementation of XML Parser 650 ⟩ +≡
constructor XMLScannObj.InitScanning(const aFileName: string);
  begin inherited Init; ⟨ Prepare to read in the contents of XML file 655 ⟩;
  nSpelling ← ``; nLine ← ``; nCurCol ← 0; nPos.Line ← 0; nPos.Col ← 0;
  GetToken;
end;

```

655. This prepares to read in from an XML file, setting up a text buffer, and opening the file in “read mode”.

```

⟨ Prepare to read in the contents of XML file 655 ⟩ ≡
  Assign(nSourceFile, aFileName); GetMem(nSourceFileBuff, InOutFileBuffSize);
  SetTextBuf(nSourceFile, nSourceFileBuff↑, InOutFileBuffSize); Reset(nSourceFile) { open for reading }

```

This code is used in section 654.

656. Destructor. We need to close the XML file, as well as free up the input buffer.

```

⟨ Implementation of XML Parser 650 ⟩ +≡
destructor XMLScannObj.Done;
  begin close(nSourceFile); FreeMem(nSourceFileBuff, InOutFileBuffSize);
  nLine ← ``; nSpelling ← ``;
  inherited Done;
end;

```

If the reader wants to extend Mizar to support UTF-8, then the *byte* parameter needs to be modified accordingly. A crude first approximation would be to set the entries indexed [128...255] to 1.

$$\langle \text{Implementation of XML Parser } 650 \rangle + \equiv$$
[illegible]

end;

On the other hand, if there is still more left in the file, we should read in a line, increment the line number, reset the column to 1, and skip over any whitespace (specifically, “SP” are skipped over — tabs or newlines are not skipped).

end

This code is used in section [657](#).

659. There are several situations when determining tokens. We will often want to keep accumulating alphanumeric characters, so we describe this in the “keep eating alphanumerics” macro.

When we encounter a “<” character, this could begin or end a tag, or it could be something special if the next character is “?” or “!”. We determine the type in the “get tag kind” macro.

```

define keep_eating_alphanumerics  $\equiv$ 
  begin nCurTokenKind  $\leftarrow$  ID;
  repeat inc(nCurCol)
  until CharKind[nLine[nCurCol]] = 0;
  end
define get_tag_kind  $\equiv$  inc(nCurCol);
  case nLine[nCurCol] of
    ‘/’: begin nCurTokenKind  $\leftarrow$  ET; inc(nCurCol); end;
    ‘?’: begin nCurTokenKind  $\leftarrow$  BI; inc(nCurCol); end;
    ‘!’: begin nCurTokenKind  $\leftarrow$  DT; inc(nCurCol); end;
  othercases nCurTokenKind  $\leftarrow$  LT;
  endcases
define keep_getting_until_end_of_tag(#)  $\equiv$  begin inc(nCurCol);
  if nLine[nCurCol] = ‘>’ then
    begin nCurTokenKind  $\leftarrow$  #; inc(nCurCol); end
  else nCurTokenKind  $\leftarrow$  Err;
  end;

```

(Get token kind based off of leading character 659) \equiv

```

case nLine[nCurCol] of
  ‘a’ .. ‘z’, ‘A’ .. ‘Z’, ‘0’ .. ‘9’, ‘_’, ‘-’, ‘&’: keep_eating_alphanumerics;
  ‘”’: begin nCurTokenKind  $\leftarrow$  QT; inc(nCurCol); end;
  ‘=’: begin nCurTokenKind  $\leftarrow$  EQ; inc(nCurCol); end;
  ‘<’: begin get_tag_kind; end;
  ‘>’: begin nCurTokenKind  $\leftarrow$  GT; inc(nCurCol); end;
  ‘/’: keep_getting_until_end_of_tag(EE);
  ‘?’: keep_getting_until_end_of_tag(EI);
othercases begin nCurTokenKind  $\leftarrow$  Err; inc(nCurCol); end;
endcases

```

This code is used in section 657.

660. Get attribute value. Scanners can obtain attribute values as tokens. This is used by the XML parser (§§665, 668). I think one possible source of bugs is that this does not handle escaped quotes (e.g., “\” is traditionally parsed as a quotation mark character).

This will not include the delimiting quotation marks, and it will also skip all whitespace *after* the attribute.

```

define skip_to_quotes  $\equiv$  while (nCurCol < length(nLine))  $\wedge$  (nLine[nCurCol]  $\neq$  ‘”’) do inc(nCurCol)
define is_space  $\equiv$  (nCurCol < length(nLine))  $\wedge$  (nLine[nCurCol]  $\in$  [‘ ’, ‘\t’, ‘\n’])
define skip_spaces  $\equiv$  while is_space do inc(nCurCol)

```

(Implementation of XML Parser 650) $+\equiv$

```

procedure XMLScannObj.GetAttrValue;
  var lCol: integer;
  begin lCol  $\leftarrow$  nCurCol; skip_to_quotes;
  nSpelling  $\leftarrow$  Copy(nLine, lCol, nCurCol - lCol); { save the lexeme }
  if nLine[nCurCol] = ‘”’ then inc(nCurCol);
  skip_spaces;
  end;

```

Section 13.2. XML PARSER

661. We recall (§648) the type for element states (it's an enumerated type with two values, *eStart* and *eEnd*).

```

⟨ Declare XML Parser object 661 ⟩ ≡
XMLParserObj = object (XMLScannObj)
  nElName: string; { name of the current element }
  nState: TElementState;
  nAttrVals: MSortedStrList;
  constructor InitParsing(const aFileName: string);
  destructor Done; virtual;
  procedure ErrorRecovery(aErr : integer; aSym : TokensSet);
  procedure NextTag; virtual;
  procedure NextElementState; virtual;
  procedure AcceptEndState; virtual;
  procedure AcceptStartState; virtual;
  procedure OpenStartTag; virtual;
  procedure CloseStartTag; virtual;
  procedure CloseEmptyElementTag; virtual;
  procedure ProcessEndTag; virtual;
  procedure ProcessAttributeName; virtual;
  procedure ProcessAttributeValue; virtual;
  procedure SetAttributeValue(const aVal: string);
end ;

```

This code is used in section 648.

662. Constructor. The parser expects an XML file to start with “<?xml ...?>” (everything after the “xml” is ignored). If this is not the first non-whitespace entry, an error will be raised.

The constructor will then skip all other “<?...?>” entities.

```

define skip_xml_prolog ≡
  while (nCurTokenKind ≠ EOTX) ∧ (nCurTokenKind ≠ EI) do GetToken;
  if nCurTokenKind = EI then GetToken
define skip_all_other_ids ≡
  while nCurTokenKind = BI do
    begin GetToken; skip_xml_prolog;
  end

```

⟨ Implementation of XML Parser 650 ⟩ +≡

```

constructor XMLParserObj.InitParsing(const aFileName: string);
begin inheritedInitScanning(aFileName); nElName ← ``; nAttrVals.Init(0);
if nCurTokenKind = BI then
  begin GetToken;
  if (nCurTokenKind = ID) ∧ (nSpelling = `xml`) then GetToken
  else ErrorRecovery(10, [EI, LT]);
  skip_xml_prolog; skip_all_other_ids; { skip all other initial processing instructions }
  end;
end;

```

663. Destructor. We will set the element name to the empty string, and invoke the destructor for the attribute values.

```
destructor XMLParserObj.Done;
  begin inherited Done; nAttrVals.Done; nElName ← ``;
end;
```

664. Error recovery. We just raise a runtime error. In fact, this is often used in situations like:

```
if nCurTokenKind = ID then { success }
else ErrorRecovery(5, [LT, ET]);
```

Consequently, it is probably more idiomatic to introduce a macro *xml_match(tokenKind)(aErr, aSym)* to assert the match and raise an error for mismatch. Unfortunately, WEB macros allow for only one argument, so we need two macros.

```
define report_mismatch(#) ≡ ErrorRecovery(#)
define xml_match(#) ≡ if nCurTokenKind ≠ # then report_mismatch
  { ErrorRecovery is no longer allowed for XML, bad XML is just RTE }
procedure XMLParserObj.ErrorRecovery(aErr : integer; aSym : TokensSet);
  begin Mizassert(errBadXMLToken, false);
end;
```

665. The parser will then consume the next tag or element. It's useful to recall the token kinds (§648).

Curiously, the attributes are skipped during this parsing function.

This will be using the inherited procedure *GetToken* (§657).

```
  { Parses next part of XML, used for skipping some part of XML }
  { setting the nState to eStart or eEnd. }
  { nElName is set properly }
  { nAttrVals are omitted (skipped). }
procedure XMLParserObj.NextTag;
  begin case nCurTokenKind of
    EOTX: nState ← eEnd; { sometimes we need this }
    LT: begin nState ← eStart; GetToken; xml_match(ID)(6, [LT, ET]); OpenStartTag; GetToken;
      ⟨ Get contents of XML start tag 666 ⟩;
    end;
    EE: begin nState ← eEnd; GetToken; end;
    ET: ⟨ Parse XML end tag 667 ⟩;
  othercases ErrorRecovery(9, [LT, ET]);
endcases;
end;
```

666. When getting the contents of an XML start tag (or possibly an element), we keep going until we get to either “\>” (for an element) or “>” (for a tag). This will be using the inherited procedure *GetToken* (§657).

```
define get_attribute  $\equiv$  begin GetToken; xml_match(EQ)(4, [ID, GT, LT, ET]); GetToken;
  xml_match(QT)(3, [ID, GT, LT, ET]); GetAttrValue; GetToken;
end
```

⟨Get contents of XML start tag 666⟩ \equiv

```
repeat case nCurTokenKind of
  GT: begin GetToken; break end;
  EE: begin break end;
  ID: get_attribute;
othercases begin ErrorRecovery(5, [GT, LT, ET]); break end;
endcases;
until nCurTokenKind = EOTX
```

This code is used in section 665.

667. ⟨Parse XML end tag 667⟩ \equiv

```
begin nState  $\leftarrow$  eEnd; GetToken; xml_match(ID)(8, [LT, ET]); OpenStartTag; GetToken;
  xml_match(GT)(7, [LT, ET]); GetToken
end
```

This code is used in section 665.

668. For Mizar, *everything* will be encoded as an element or an attribute on an element. So we do not really need to consider the case where we would encounter text in the body of an element.

⟨Implementation of XML Parser 650⟩ \equiv

{ Parses next part of XML, setting the *nState* to *eStart* or *eEnd*. If *nState* = *eStart*, then *nElName*, *nAttrVals* are set properly. It is possible to go from *nState* = *eStart* to *nState* = *eStart* (when the element is non empty), and similarly from *eEnd* to *eEnd*. }

procedure *XMLParserObj.NextElementState*;

```
begin case nCurTokenKind of
  EOTX: nState  $\leftarrow$  eEnd; { sometimes we need this }
  LT: ⟨Parse start of XML tag 669⟩;
  EE: begin nState  $\leftarrow$  eEnd; GetToken; end;
  ET: begin nState  $\leftarrow$  eEnd; GetToken; xml_match(ID)(8, [LT, ET]); ProcessEndTag; GetToken;
    xml_match(GT)(7, [LT, ET]); GetToken; end;
othercases ErrorRecovery(9, [LT, ET]);
endcases;
end;
```

669. We start parsing a start-tag because we have encountered an LT token. So at this point, the next token should be an identifier of some kind. A start-tag may actually be an empty-element tag, so we need to look out for the *EE* token kind.

Note: the XML parser does not handle comments, otherwise we would need to consider that situation here.

```

define end_start_tag  $\equiv$  begin GetToken; CloseStartTag; break end
define end_empty_tag  $\equiv$  begin CloseEmptyElementTag; break end
⟨ Parse start of XML tag 669 ⟩  $\equiv$ 
begin nState  $\leftarrow$  eStart; GetToken; xml_match(ID)(6, [LT, ET]); OpenStartTag;
    { Start-Tag or Empty-Element-Tag Name = nSpelling }
    GetToken;
repeat case nCurTokenKind of
    GT: end_start_tag; { End of a Start-Tag }
    EE: end_empty_tag; { End of a Empty-Element-Tag }
    ID: begin ProcessAttributeName; GetToken; xml_match(EQ)(4, [ID, GT, LT, ET]); GetToken;
        xml_match(QT)(3, [ID, GT, LT, ET]); GetAttrValue; ProcessAttributeValue; GetToken;
        end;
    othercases begin ErrorRecovery(5, [GT, LT, ET]); break end;
endcases;
until nCurTokenKind = EOTX;
end

```

This code is used in section 668.

670. We will want assertions reflecting the parser is in a “start” state or an “end” state.

```

⟨ Implementation of XML Parser 650 ⟩  $+\equiv$ 
procedure XMLParserObj.AcceptEndState;
    begin NextElementState; MizAssert(errElRedundant, nState = eEnd);
    end;
procedure XMLParserObj.AcceptStartState;
    begin NextElementState; MizAssert(errElMissing, nState = eStart);
    end;

```

671. ⟨ Implementation of XML Parser 650 ⟩ $+\equiv$

```

procedure XMLParserObj.OpenStartTag;
    begin nElName  $\leftarrow$  nSpelling; nAttrVals.FreeAll;
    end;

```

672. We have a few procedures which are, well, empty. I am not sure why we have them. Regardless, here they are!

```

procedure XMLParserObj.CloseStartTag;
    begin end;
procedure XMLParserObj.CloseEmptyElementTag;
    begin end;
procedure XMLParserObj.ProcessEndTag;
    begin end;

```

673. We have a list of attributes. When the parser *ProcessAttributeName*, it will merely push a new *XMLAttrPtr* to the list with the given name. Then *ProcessAttributeValue* will associate to it the value which has been parsed. We can, of course, *manually* set the value for an attribute using *SetAttributeValue*.

```

procedure XMLParserObj.ProcessAttributeName;
  begin nAttrVals.Insert(new(XMLAttrPtr, Init(nSpelling, ``)));
  end;

procedure XMLParserObj.ProcessAttributeValue;
  begin SetAttributeValue(nSpelling);
  end;

procedure XMLParserObj.SetAttributeValue(const aVal: string);
  begin with nAttrVals do XMLAttrPtr(Items↑[Count - 1])↑.nValue ← aVal;
  end;

```

File 14

I/O with XML

674. We will want to print some XML to a buffer or stream.

Note that XML seems to be frozen at version 1.0 (first published in 1998, last revised in its fifth edition released November 26, 2008).

```

⟨xml_inout.pas 674⟩ ≡
  ⟨GNU License 4⟩
unit xml_inout;
  interface
    uses errhan, mobjects, xml_parser;
    ⟨Type declarations for XML I/O 675⟩
    function QuoteStrForXML(const aStr: string): string;
    function XMLToStr(const aXMLStr: string): string;
    function QuoteXMLAttr(aStr : string): string;
    const gXMLHeader = `<?xml version="1.0"?>` + #10;
  implementation
    uses SysUtils, mizenv, pcmizver, librenv, xml_dict
    mdebug , info end_mdebug;
  ⟨Implementation for I/O of XML 676⟩
end .

```

675. There are only 4 types of streams we care about: Streams, Text Streams, XML Input Streams, and XML Output Streams.

```

⟨Type declarations for XML I/O 675⟩ ≡
  ⟨Public interface for XML Input Stream 688⟩;
  ⟨Public declaration for Stream Object 680⟩;
  ⟨Public declaration for Text Stream Object 684⟩;
  ⟨Public declaration for XML Output Stream 693⟩;

```

This code is used in section 674.

676. Escape for quote string. We want to allow only alphanumerics [a-zA-Z0-9] as well as dashes (“-”), spaces (“ ”), commas (“,”), periods (“.”), apostrophes (“’”), forward slashes (“/”), underscores (“_”), brackets (“[” and “]”), exclamation points (“!”), semicolons and colons (“;” and “:”), and equal signs (“=”). Everything else we transform into an XML entity of the form “&xx” where **x** is a hexadecimal digit.

⟨Implementation for I/O of XML 676⟩ ≡

```
function QuoteStrForXML(const aStr: string): string;
  const ValidCharTable = ([‘a’ .. ‘z’, ‘A’ .. ‘Z’, ‘0’ .. ‘9’, ‘-’, ‘_’, ‘ ’, ‘,’, ‘.’, ‘\’, ‘/’, ‘_’, ‘[’, ‘]’,
    ‘!’, ‘;’, ‘:’, ‘=’]);
  var c: char; i: integer;
  begin result ← aStr;
  for i ← length(result) downto 1 do
    begin c ← result[i];
    if ¬(c ∈ ValidCharTable) then
      begin result[i] ← ‘&’; Insert(‘#x’ + IntToHex(Ord(c), 2) + ‘’, result, i + 1);
      end;
    end;
  end;
```

See also sections 679, 681, 685, 689, 694, and 700.

This code is used in section 674.

677. This appears to “undo” the previous function, transforming XML entities of the form “&xx” into characters.

```
function XMLToStr(const aXMLStr: string): string;
  var i, h: integer; lHexNr: string;
  begin result ← aXMLStr;
  for i ← length(result) - 5 downto 1 do
    begin ⟨Transform XML entity into character, if encountering an XML entity at i 678⟩;
    end;
  result ← Trim(result);
  end;
```

678. Transforming an XML entity into a character. This specifically checks for *hexadecimal* entities of the form “&#xXX” for some hexadecimal digits *X*. Note we must prepend “0x” to a numeric string for PASCAL to parse it as hexadecimal.

Since PASCAL does not have shortcircuiting Boolean operations, we need to make this a nested **if** statement.

⟨Transform XML entity into character, if encountering an XML entity at i 678⟩ ≡

```
if (result[i] = ‘&’) ∧ (length(result) ≥ i + 5) then
  begin if (result[i + 1] = ‘#’) ∧ (result[i + 2] = ‘x’) then
    begin lHexNr ← result[i + 3] + result[i + 4]; h ← StrToInt(‘0x’ + lHexNr); Delete(result, i, 5);
    result[i] ← chr(h);
    end;
  end
```

This code is used in section 677.

679. We can quote an XML attribute, escaping quotes, ampersands, and angled brackets. For non-ASCII characters, we escape it to a hexadecimal XML entity.

⟨Implementation for I/O of XML 676⟩ +≡

```
function QuoteXMLAttr(aStr : string): string;
  var i: integer;
  begin result ← ``;
  for i ← 1 to length(aStr) do
    case aStr[i] of
      `"`: result ← result + `&quot;;`
      `&`: result ← result + `&amp;;`
      `<`: result ← result + `&lt;;`
      `>`: result ← result + `&gt;;`
      othercases if integer(aStr[i]) > 127 then result ← result + `&#x` + IntToHex(Ord(aStr[i]), 2) + `;`
        else result ← result + aStr[i];
      endcases;
    end;
```

680. Stream object class. A stream consists of a file, a character buffer, as well as integers tracking the size of the buffer and (I think) the position in the buffer. This is the parent class to XML output buffers.

⟨Public declaration for Stream Object 680⟩ ≡

```
StreamObj = object (MObject)
  nFile: File;
  fFileBuff: ↑BuffChar;
  fBuffCount, fBuffInd: longint;
  constructor InitFile(const AFileName: string);
  procedure Error(Code, Info : integer); virtual;
  destructor Done; virtual;
end
```

This code is used in section 675.

681. We will have a wrapper function for conveniently reporting errors.

⟨Implementation for I/O of XML 676⟩ +≡

```
procedure StreamObj.Error(Code, Info : integer);
  begin RunError(2000 + Code);
  end;
```

682. Constructor. We begin by *Assign*-ing a name to a file, allocating a file buffer, then initializing the buffer size to zero, and the buffer position to zero. (The buffer position *fBuffInd* is needed only when writing to an output XML stream.)

```
constructor StreamObj.InitFile(const AFileName: string);
  begin Assign(nFile, AFileName); new(fFileBuff); fBuffCount ← 0; fBuffInd ← 0;
  end;
```

683. Destructor. We close the file, and free up the file buffer.

```
destructor StreamObj.Done;
  begin Close(nFile); dispose(fFileBuff);
  end;
```

684. Text Stream Object. A text stream is very similar to a Stream Object, except it is specifically for text.

```

⟨Public declaration for Text Stream Object 684⟩ ≡
  TXTStreamObj = object (MObject)
    nFile: text;
    nFileBuff: pointer;
    constructor InitFile(const AFileName: string);
    procedure Error(Code, Info : integer); virtual;
    destructor Done; virtual;
  end

```

This code is used in section 675.

685. We have the convenience function for reporting errors.

```

⟨Implementation for I/O of XML 676⟩ +≡
procedure TXTStreamObj.Error(Code, Info : integer);
  begin RunError(2000 + Code);
  end;

```

686. Constructor. Assign a name to the file, allocate an input buffer, then initialize the buffer.

```

constructor TXTStreamObj.InitFile(const AFileName: string);
  begin Assign(nFile, AFileName); GetMem(nFileBuff, InOutFileBuffSize);
  SetTextBuf(nFile, nFileBuff↑, InOutFileBuffSize);
  end;

```

687. Destructor. Simply free the underlying file buffer.

```

destructor TXTStreamObj.Done;
  begin FreeMem(nFileBuff, InOutFileBuffSize);
  end;

```

688. XML Input Streams. An input stream reads an XML file and produces an abstract syntax tree for its contents. This extends this XML parser class (§661). It may be tempting to draw similarities with, e.g., the StAX library (in Java), but the truth is there's only finitely many ways to parse XML, and some ways are just more natural.

```

⟨Public interface for XML Input Stream 688⟩ ≡
  XMLInStreamPtr = ↑XMLInStreamObj;
  XMLInStreamObj = object (XMLParserObj)
    constructor OpenFile(const AFileName: string);
    function GetOptAttr(const aAttrName: string; var aVal: string) : boolean;
    function GetAttr(const aAttrName: string): string;
    function GetIntAttr(const aAttrName: string): integer;
  end

```

This code is used in section 675.

689. Constructor. The non-debugging code just invokes the XML Parser's constructor (§662).

```

⟨Implementation for I/O of XML 676⟩ +≡
constructor XMLInStreamObj.OpenFile(const AFileName: string);
  begin
    mdebug ; write(InfoFile, AFileName); end_mdebug;
    InitParsing(AFileName);
    mdebug ; WriteLn(InfoFile, 'reset'); end_mdebug;
  end;

```

690. We use the inherited *XMLParserObj*'s *nAttrVals*: *MSortedStrList* to track the XML attributes. If *aAttrName* is stored there, this will mutate *aVal* to store the associated value and the function will return *true*. Otherwise, this will return *false*.

This is useful for getting the value of an *optional* XML attribute.

```
{ get string denoted by optional XML attribute aAttrName }
function XMLInStreamObj.GetOptAttr (const aAttrName: string; var aVal: string) : boolean;
var lAtt: XMLAttrPtr;
begin lAtt ← XMLAttrPtr(nAttrVals.ObjectOf(aAttrName));
if lAtt ≠ nil then
  begin aVal ← lAtt↑.nValue; GetOptAttr ← true; exit;
  end;
  GetOptAttr ← false;
end;
```

691. When we know an XML attribute is *required*, we can just get the associated value directly (and raise an error if it is missing).

```
{ get string denoted by required XML attribute aAttrName }
function XMLInStreamObj.GetAttr(const aAttrName: string): string;
var lAtt: XMLAttrPtr;
begin lAtt ← XMLAttrPtr(nAttrVals.ObjectOf(aAttrName));
if lAtt ≠ nil then
  begin GetAttr ← lAtt↑.nValue; exit;
  end;
  MizAssert(errMissingXMLAttribute, false);
end;
```

692. When the required attribute has an integer value, we should return the integer-value of it. Does this ever happen? Yes! For example, when writing an article named `article.miz`, then we run the verifier on it, we shall obtain `article.xml` which will contain tags of the form “<Adjective nr="5">”.

```
{ get integer denoted by required XML attribute aAttrName }
function XMLInStreamObj.GetIntAttr(const aAttrName: string): integer;
var lInt, ec: integer;
begin val(GetAttr(aAttrName), lInt, ec); GetIntAttr ← lInt;
end;
```

693. XML Output Streams. We will want to write data to an XML file. This gives us an abstraction for doing so.

```

⟨Public declaration for XML Output Stream 693⟩ ≡
  XMLOutputStreamPtr = ↑XMLOutputStreamObj;
  XMLOutputStreamObj = object (StreamObj)
    nIndent: integer; { indenting }
    constructor OpenFile(const AFileName: string);
    constructor OpenFileWithXSL(const AFileName: string);
    destructor EraseFile;
    procedure OutChar(AChar : char);
    procedure OutNewLine;
    procedure OutString(const AString: string);
    procedure OutIndent;
    procedure Out_XElStart(const fEl: string);
    procedure Out_XAttrEnd;
    procedure Out_XElStart0(const fEl: string);
    procedure Out_XElEnd0;
    procedure Out_XEl1(const fEl: string);
    procedure Out_XElEnd(const fEl: string);
    procedure Out_XAttr(const fAt, fVal: string);
    procedure Out_XIntAttr(const fAt: string;
      fVal: integer);
    procedure Out_PosAsAttrs(const fPos: Position);
    procedure Out_XElWithPos(const fEl: string;
      const fPos: Position);
    procedure Out_XQuotedAttr(const fAt, fVal: string);
    destructor Done; virtual;
  end

```

This code is used in section 675.

694. Constructor. We initialize a file, open it for writing, set the initial indentation amount to zero, and then print the XML header declaration.

```

⟨Implementation for I/O of XML 676⟩ +≡
constructor XMLOutputStreamObj.OpenFile(const AFileName: string);
  begin
    mdebug write(InfoFile, MizFileName + `.` + copy(AFileName, length(AFilename) - 2, 3));
    end_mdebug
    InitFile(AFileName); Rewrite(nFile, 1);
    mdebug WriteLn(InfoFile, `rewritten`); end_mdebug
    nIndent ← 0; OutString(gXMLHeader);
  end;

```

695. Constructor. Since XML supports custom style declarations (think of XSLT), we can also support writing an XML file which uses them. This specifically needs to adjust the XML declaration.

```

  { add the stylesheet procesing info }
constructor XMLOutputStreamObj.OpenFileWithXSL(const AFileName: string);
  begin OpenFile(AFileName);
    OutString(`<?xml-stylesheet`_type="text/xml"`_href="file://` + MizFiles + `miz.xml"?` + #10);
  end;

```

696. Destructor. We need to flush the buffer to the file before freeing up the buffer.

```

destructor XMLOutStreamObj.Done;
  begin if (fBuffInd > 0)  $\wedge$  (fBuffInd < InOutFileBuffSize) then
    BlockWrite(nFile, fFileBuff↑, fBuffInd, fBuffCount);
  inherited Done;
  end;

```

697. Destructor. Some times we want to further erase the output file (which seems, at first glance, like a really bad idea...).

```

destructor XMLOutStreamObj.EraseFile;
  begin Done; Erase(nFile);
  end;

```

698. Writing a character to the buffer. When the buffer is full, we flush it.

```

procedure XMLOutStreamObj.OutChar(aChar : char);
  begin fFileBuff↑[fBuffInd] ← AnsiChar(aChar); inc(fBuffInd); ⟨Flush XML output buffer, if full 699⟩;
  end;

```

699. The XML output buffer is full when the logical size (fBuffInd) is equal to the InOutFileBuffSize. When this happens, we should write everything to the file, then reset the logical size parameter to zero.

```

⟨Flush XML output buffer, if full 699⟩ ≡
  if fBuffInd = InOutFileBuffSize then
    begin BlockWrite(nFile, fFileBuff↑, InOutFileBuffSize, fBuffCount); fBuffInd ← 0;
    end

```

This code is used in section 698.

700. Print a newline ("␣") to the XML output stream.

```

⟨Implementation for I/O of XML 676⟩ +≡
procedure XMLOutStreamObj.OutNewLine;
  begin OutChar(#10);
  end;

```

701. Printing a string to the output buffer.

```

procedure XMLOutStreamObj.OutString(const aString: string);
  var i: integer;
  begin for i ← 1 to length(aString) do OutChar(aString[i]);
  end;

```

702. Printing nIndent spaces ("␣") to the output buffer.

```

{ print nIndent spaces }
procedure XMLOutStreamObj.OutIndent;
  var i: integer;
  begin for i ← 1 to nIndent do OutChar('␣');
  end;

```

703. When printing a start-tag to the file, we start by printing the indentation, then we increment the indentation, then we print the “<” followed by the name of the tag.

```
{ print '<' and the representation of fEl with indenting }
procedure XMLOutStreamObj.Out_XElStart(const fEl: string);
  begin OutIndent; inc(nIndent); OutChar('<'); OutString(fEl);
  end;
```

704. When we are done writing the attributes of a tag, we print the “>” to the file, and we also print a newline to the file.

```
{ close the attributes with '>' }
procedure XMLOutStreamObj.Out_XAttrEnd;
  begin OutChar('>'); OutNewLine;
  end;
```

705. When we want to write the tag, but omit the attributes, we can do so.

```
{ no attributes expected }
procedure XMLOutStreamObj.Out_XElStart0(const fEl: string);
  begin Out_XElStart(fEl); Out_XAttrEnd;
  end;
```

706. For empty-element tags, we should close the tag with “/>”, print a new line, then *decrement* the indentation since there are no children to the tag.

```
{ print '/>' with indenting }
procedure XMLOutStreamObj.Out_XElEnd0;
  begin OutString('>'); OutNewLine; dec(nIndent);
  end;
```

707. When printing an empty-element tag without any attributes, we can combine the preceding functions together.

```
{ no attributes and elements expected }
procedure XMLOutStreamObj.Out_XEl1(const fEl: string);
  begin Out_XElStart(fEl); Out_XElEnd0;
  end;
```

708. Printing end-tags should first decrement the indentation *before* printing the indentation to the file (so that the end-tag vertically aligns with the associated start-tag). Then we print “</” followed by the tag name and then “>”. We should print a newline to the file, too.

```
{ close the fEl element using '</' }
procedure XMLOutStreamObj.Out_XElEnd(const fEl: string);
  begin dec(nIndent); OutIndent; OutString('</'); OutString(fEl); OutChar('>'); OutNewLine;
  end;
```

709. When printing one attribute to a tag, we need a whitespace printed (to separate the tag’s name — or preceding attribute — from the current attribute being printed), followed by the attribute’s name printed with an equality symbol, then enquoted the value of the attribute.

```
{ print one attribute key-value pair }
procedure XMLOutStreamObj.Out_XAttr(const fAt, fVal: string);
  begin OutChar(' '); OutString(fAt); OutString('=''); OutString(fVal); OutChar('"');
  end;
```

710. When the value of an attribute is an integer, invoke *IntToStr(fVal)* to pretend it is a string value. Then printing out to a file an attribute with an integer value boils down to printing out the attribute with a string value.

```
{ print one attribute key-value pair, where value is integer }
procedure XMLOutStreamObj.Out_XIntAttr(const fAt: string; fVal: integer);
  begin Out_XAttr(fAt, IntToStr(fVal));
  end;
```

711. We can now just compose writing the start of a tag (§703), followed by its attributes (§712), and then close the empty-element tag (§706).

```
procedure XMLOutStreamObj.Out_XElWithPos(const fEl: string; const fPos: Position);
  begin Out_XElStart(fEl); Out_PosAsAttrs(fPos); Out_XElEnd0;
  end;
```

712. We will want to treat a *position* (i.e., the line and column) as two attributes. We print this out using *Out_PosAsAttrs*. We rely on the *XMLDict*'s *XMLAttrName* for standardizing the name for the line and column.

```
procedure XMLOutStreamObj.Out_PosAsAttrs(const fPos: Position);
  begin Out_XIntAttr(XMLAttrName[atLine], fPos.Line);
  Out_XIntAttr(XMLAttrName[atCol], fPos.Col);
  end;
```

713. We print a quoted attribute, leveraging printing attributes out to the file (§709). We just need to escape the XML string (§676).

```
procedure XMLOutStreamObj.Out_XQuotedAttr(const fAt, fVal: string);
  begin Out_XAttr(fAt, QuoteStrForXML(fVal));
  end;
```

File 15

Vocabulary file dictionaries

714. Mizar works with vocabulary files (suffixed with `.voc`) for introducing new identifiers.

```

⟨dicthan.pas 714⟩ ≡
  ⟨GNU License 4⟩
unit dicthan;
interface
  uses mobjects;
  ⟨Public constants for dicthan.pas 715⟩
  type SymbolCounters = array [^A .. ^Z] of word;
    SymbolIntSeqArr = array [^A .. ^Z] of IntSequence;
  ⟨Class declarations for dicthan.pas 716⟩
  ⟨Public function declarations for dicthan.pas 717⟩
implementation
  uses mizenv, xml_inout, xml_dict;
  ⟨Implementation for dicthan.pas 718⟩
end .

```

715. We recall from Adam Grabowski, Artur Kornilowicz, and Adam Naumowicz’s “Mizar in a Nutshell” (§4.3, [doi:10.6092/issn.1972-5787/1980](https://doi.org/10.6092/issn.1972-5787/1980)), the various prefixes for vocabulary file entries:

- G for structures
- K for left-functor brackets
- L for right-functor brackets
- M for modes
- O for functors
- R for predicates
- U for selectors
- V for attributes

```

⟨Public constants for dicthan.pas 715⟩ ≡
const
  StandardPriority = 64;
  AvailableSymbols = [^G, ^K, ^L, ^M, ^O, ^R, ^U, ^V];

```

This code is used in section 714.

716. There are only three classes in the dictionary handling module. We have an abstraction for a symbol appearing in a vocabulary file, a sort of “checksum” for the counts of symbols appearing in a vocabulary file, and a dictionary associating to each article name (string) a collection of symbols.

```

⟨Class declarations for dicthan.pas 716⟩ ≡
  ⟨Symbol for vocabulary 722⟩;
  ⟨Abstract vocabulary object declaration 731⟩;
  ⟨Vocabulary object declaration 733⟩;

```

This code is used in section 714.

717. \langle Public function declarations for `dicthan.pas` 717 $\rangle \equiv$
function *GetPrivateVoc*(**const** *fName*: *string*): *PVocabulary*;
function *GetPublicVoc* (**const** *fName*: *string*; **var** *fVocFile*: *text*) : *PVocabulary*;
procedure *LoadMmlVcb* (**const** *aFileName*: *string*; **var** *aMmlVcb*: *MStringList*) ;
procedure *StoreMmlVcb*(**const** *aFileName*: *string*; **const** *aMmlVcb*: *MStringList*);
procedure *StoreMmlVcbX*(**const** *aFileName*: *string*; **const** *aMmlVcb*: *MStringList*);

This code is used in section 714.

718. We can test if an entry in the dictionary is valid. Remember, only functor symbols can have a priority associated with it (and a priority is a number between 0 and $2^8 - 1$, inclusive).

Also remember, that a symbol in a dictionary entry **cannot** have whitespaces in it.

define *delete_prefix* \equiv *Delete*(*lLine*, 1, 1)

\langle Implementation for `dicthan.pas` 718 $\rangle \equiv$
function *IsValidSymbol*(**const** *aLine*: *string*): *boolean*;
var *lLine*: *string*; *lKind*: *char*; *lPriority*, *lPos*, *lCode*: *integer*;
begin *IsValidSymbol* \leftarrow *false*; *lLine* \leftarrow *TrimString*(*aLine*);
 \langle Initialize *lKind*, but exit if dictionary line contains invalid symbol 719 \rangle ;
delete_prefix;
case *lKind* **of**
 '0' : \langle Check if functor symbol is valid 720 \rangle ;
 'R' : \langle Check if predicate symbol is valid 721 \rangle ;
othercases **begin** **if** *Pos*('\u00a0' , *lLine*) > 0 **then** *exit*;
IsValidSymbol \leftarrow *true*;
end;
endcases;
end;

See also sections 723, 727, 732, 734, 738, 740, and 741.

This code is used in section 714.

719. An “invalid” line in the dictionary file would be empty lines (whose length is less than one), and lines which do not start with a valid prefix. At the end of this chunk, the *lKind* should be initialized to the prefix of the line.

\langle Initialize *lKind*, but exit if dictionary line contains invalid symbol 719 $\rangle \equiv$
if *length*(*lLine*) \leq 1 **then** *exit*;
lKind \leftarrow *lLine*[1];
if \neg (*lKind* \in *AvailableSymbols*) **then** *exit*

This code is used in section 718.

720. Recall the [specification](#) for *Val* sets *lCode* to zero for success, and the nonzero values store the index where the string is not a numeric value.

We copy the identifier (as determined from the start of the line until, but not including, the index of the first space in the line) and throw away everything after the first whitespace.

When the identifier for the functor symbol is not an empty string *and* the priority can be determined unambiguously, then the functor symbol entry is valid. Otherwise it is invalid.

⟨ Check if functor symbol is valid [720](#) ⟩ ≡

```

begin IsValidSymbol ← true; lPos ← Pos(‘␣’, lLine);
if lPos ≠ 0 then
  begin { Parse priority for symbol }
    val (TrimString(Copy(lLine, lPos, length(lLine))), lPriority, lCode);
    lLine ← TrimString(Copy(lLine, 1, lPos - 1)); IsValidSymbol ← (lCode = 0) ∧ (lLine ≠ ‘’);
  end;
end

```

This code is used in section [718](#).

721. A predicate entry in the dictionary file should not include a priority, nor should it include any whitespaces. This is the criteria for a valid predicate symbol entry in the dictionary.

We enforce this by finding the first “␣” character in the line. If there is one, then we trim both sides of the line (removing leading and trailing whitespace). We should have no more spaces in the line. If there is a space, then it is an invalid predicate symbol.

⟨ Check if predicate symbol is valid [721](#) ⟩ ≡

```

begin lPos ← Pos(‘␣’, lLine);
if lPos ≠ 0 then { lLine contains a space }
  begin lLine ← TrimString(Copy(lLine, lPos, length(lLine)));
    if Pos(‘␣’, lLine) > 0 then exit;
  end;
  IsValidSymbol ← true;
end

```

This code is used in section [718](#).

722. TSymbol. These are used in `kernel/accdict.pas`. The *Kind* is its one-letter kind (discussed in [§715](#)), and *Repr* is its lexeme. For functors, its priority is stored as its *Prior*.

The “infinite” appears to be only used for predicates.

⟨ Symbol for vocabulary [722](#) ⟩ ≡

```

PSymbol = ↑TSymbol;
TSymbol = object (MObject)
  Kind: char;
  Repr, Infinitive: string;
  Prior: byte;
constructor Init(fKind: char; fRepr, fInfinitive: string; fPriority: byte);
constructor Extract(const aLine: string);
function SymbolStr: string;
constructor Load(var aText: text);
procedure Store(var aText: text);
destructor Done; virtual;
end

```

This code is used in section [716](#).

723. Constructor. Given the “kind”, its “representation” and “infinitive”, and its priority (as a number between 0 and 255), we can construct a symbol.

⟨Implementation for `dicthan.pas` 718⟩ +≡

```
constructor TSymbol.Init(fKind : char; fRepr, fInfinitive : string; fPriority : byte);
  begin Kind ← fKind; Repr ← fRepr; Prior ← fPriority; Infinitive ← ``;
end;
```

724. Constructor. When we want to extract a symbol from a line in the dictionary file, care must be taken for functors (since they may contain an explicit priority) and for predicates. Predicates have an undocumented feature to allow “infinitives”, so an acceptable predicate line in a dictionary may look like

`Rpredicate infinitive`

Although what Mizar does with infinitives, I do not know...

```
constructor TSymbol.Extract(const aLine : string);
  var lPos, lCode : integer; lRepr : string;
  begin Kind ← aLine[1]; Repr ← TrimString(Copy(aLine, 2, length(aLine))); Prior ← 0;
  Infinitive ← ``;
  case Kind of
    '0': begin lPos ← Pos('□', Repr); Prior ← StandardPriority;
      if lPos ≠ 0 then ⟨Initialize explicit priority for functor entry in dictionary 726⟩;
      end;
    'R': begin lPos ← Pos('□', Repr);
      if lPos ≠ 0 then ⟨Initilize explicit infinitive for a predicate entry in dictionary 725⟩;
      end;
  endcases;
end;
```

725. Predicates can have an optional infinitive, separated from the lexeme by a single whitespace. It remains unclear what Mizar uses predicate infinitives for, but it is a feature. This is written out to the `.vcx` file, according to `xml_dict.pas`.

Note that there are 4 predicates with infinitives in Mizar:

- (1) `jumps_in` (infinitive: `jump_in`) occurs in the article `AMISTD_1`
- (2) `halts_in` (infinitive: `halt_in`) occurs in the article `EXTPRO_1`
- (3) `refers` (infinitive: `refer`) occurs in the article `SCMFSA7B`
- (4) `destroys` (infinitive: `destroy`) occurs in the article `SCMFSA7B`

⟨Initilize explicit infinitive for a predicate entry in dictionary 725⟩ ≡

```
begin lRepr ← Repr; Repr ← ``; Repr ← TrimString(Copy(lRepr, 1, lPos - 1));
  Infinitive ← TrimString(Copy(lRepr, lPos + 1, length(lRepr)));
end
```

This code is used in section 724.

726. Functors with explicit priorities require parsing that priority. It is assumed that a single whitespace separates the lexeme from the priority.

⟨Initialize explicit priority for functor entry in dictionary 726⟩ ≡

```
begin lRepr ← Repr; Repr ← ``;
  val (TrimString(Copy(lRepr, lPos + 1, length(lRepr))), Prior, lCode); { Store the priority }
  Repr ← TrimString(Copy(lRepr, 1, lPos - 1)); { Store the lexeme }
end
```

This code is used in section 724.

727. Serialize symbols. We can serialize a *TSymbol* object, which produces the sort of entry we'd expect to find in a dictionary. So we would have the symbol kind, the lexeme, and optional data (non-default priorities for functors, infinitives for predicates).

(Implementation for `dicthan.pas` 718) \equiv

```
function TSymbol.SymbolStr: string;
  var lStr, lntStr: string;
  begin lStr  $\leftarrow$  Kind + Repr;
  case Kind of
    '0': if Prior  $\neq$  StandardPriority then
      begin Str(Prior, lntStr); lStr  $\leftarrow$  lStr + '␣' + lntStr;
      end;
    'R': if Infinitive  $\neq$  '' then lStr  $\leftarrow$  lStr + '␣' + Infinitive;
  endcases;
  SymbolStr  $\leftarrow$  lStr;
end;
```

728. Given a text (usually the contents of a vocabulary file), we read in a line. When the line is a nonempty string, we initialize the lexeme representation, priority, and infinitives. Then, when the dictionary entry describes a valid symbol (§718), we populate the fields of the *TSymbol*.

```
constructor TSymbol.Load(var aText : text);
  var lDictLine: string;
  begin ReadLn(aText, lDictLine); lDictLine  $\leftarrow$  TrimString(lDictLine);
  if length(lDictLine) = 0 then exit;
  Repr  $\leftarrow$  ''; Prior  $\leftarrow$  0; Infinitive  $\leftarrow$  '';
  if IsValidSymbol(lDictLine) then Extract(lDictLine);
end;
```

729. Storing a *TSymbol* in a file amounts to writing its serialization (§727) to the file.

```
procedure TSymbol.Store(var aText : text);
  begin WriteLn(aText, SymbolStr);
end;
```

730. Destructor. We just reset the lexeme and infinitive strings to be empty strings.

```
destructor TSymbol.Done;
  begin Repr  $\leftarrow$  ''; Infinitive  $\leftarrow$  '';
end;
```

731. Abstract vocabulary objects. This is used in `kernel/impobjs.pas`. We recall (§714) that the *SymbolCounters* are just an enumerated type consisting of a single uppercase Latin Letter.

(Abstract vocabulary object declaration 731) \equiv

```
AbsVocabularyPtr =  $\uparrow$ AbsVocabularyObj;
AbsVocabularyObj = object (MObject)
  fSymbolCnt: SymbolCounters;
  constructor Init;
  destructor Done; virtual;
end
```

This code is used in section 716.

732. We only have the constructor and destructor for abstract vocabulary objects.

⟨Implementation for `dicthan.pas` 718⟩ +≡
constructor *AbsVocabularyObj.Init*;
 begin *FillChar(fSymbolCnt, SizeOf(fSymbolCnt), 0)*;
 end;
destructor *AbsVocabularyObj.Done*;
 begin end;

733. Vocabulary objects. A “vocabulary object” is just a collection of *PSymbols* read in from a vocabulary file.

These are also used in `kernel/accdict.pas`.

⟨Vocabulary object declaration 733⟩ ≡
PVocabulary = ↑*TVocabulary*;
TVocabulary = **object** (*AbsVocabularyObj*)
 Reprs: MCollection;
 constructor *Init*;
 constructor *ReadPrivateVoc(const aFileName: string)*;
 constructor *LoadVoc(var aText: text)*;
 procedure *StoreVoc(const aFileName: string; var aText: text)* ;
 destructor *Done; virtual*;
 end

This code is used in section 716.

734. Constructor (Empty vocabulary). We can construct the empty vocabulary by just initializing the underlying collection.

⟨Implementation for `dicthan.pas` 718⟩ +≡
constructor *TVocabulary.Init*;
 begin *FillChar(fSymbolCnt, SizeOf(fSymbolCnt), 0)*; *Reprs.Init(10, 10)*;
 end;

735. Destructor. We only need to free up the underlying collection.

destructor *TVocabulary.Done*;
 begin *Reprs.Done*;
 end;

736. Constructor. We can read from a private vocabulary file.

constructor *TVocabulary.ReadPrivateVoc(const aFileName: string)*;
 var *lDict: text; lDictLine: string; lSymbol: PSymbol*;
 begin *Init; Assign(lDict, aFileName)*;
 without_io_checking(reset(lDict));
 if *ioresult* ≠ 0 **then** *exit*; { file is not ready to be read, bail out! }
 while ¬*seekEOF(lDict)* **do** ⟨Read line into vocabulary from dictionary file 737⟩;
 Close(lDict);
 end;

737. When reading dictionary lines into a vocabulary file, we skip over blank lines. Further, we only read *valid* entries into the vocabulary.

```

⟨ Read line into vocabulary from dictionary file 737 ⟩ ≡
  begin readln(lDict, lDictLine); lDictLine ← TrimString(lDictLine);
  if length(lDictLine) > 1 then { if dictionary line is not blank }
    begin lSymbol ← new(PSymbol, Extract(lDictLine));
    if IsValidSymbol(lDictLine) then { add the symbol }
      begin inc(fSymbolCnt[lSymbol↑.Kind]); Reprs.Insert(lSymbol); end;
    end;
  end
end

```

This code is used in section 736.

738. Constructor. We can read in the vocabulary from a file. If I am not mistaken, this is usually from `mml.vct`. We have the first line look like “G3 K0 L0 M1 07 R2 U4 V6”, which enumerates the number of different types of definitions appearing in an article.

```

⟨ Implementation for dicthan.pas 718 ⟩ +≡
constructor TVocabulary.LoadVoc(var aText : text);
  var i, lSymbNbr, lNbr: integer; lKind, lDummy, c: Char;
  begin lSymbNbr ← 0; ⟨ Count lNbr the number of dictionary entries for an article 739 ⟩;
  ReadLn(aText); Reprs.Init(10, 10);
  for i ← 1 to lSymbNbr do
    begin Reprs.Insert(new(PSymbol, Load(aText)));
    end;
  end;
end;

```

739. Since the first line counts the different sorts of definitions appearing in the article, we can parse the numbers, then add them up. This initializes the *fSymbolCnt* entry for *c*.

```

⟨ Count lNbr the number of dictionary entries for an article 739 ⟩ ≡
  for c ← 'A' to 'Z' do
    if c ∈ AvailableSymbols then
      begin Read(aText, lKind, lNbr, lDummy); fSymbolCnt[c] ← lNbr; Inc(lSymbNbr, fSymbolCnt[c]);
      end
    end
  end

```

This code is used in section 738.

740. Storing a dictionary entry. This appends to a `.vct` file the entries for an article. Specifically, this is just the “#ARTICLE” and then the counts of the different kinds of definitions.

```

⟨ Implementation for dicthan.pas 718 ⟩ +≡
procedure TVocabulary.StoreVoc (const aFileName: string; var aText: text );
  var i: Byte; c: Char;
  begin WriteLn(aText, '#', aFileName);
  for c ← 'A' to 'Z' do
    if c ∈ AvailableSymbols then Write(aText, c, fSymbolCnt[c], ' ');
  WriteLn(aText);
  for i ← 0 to Reprs.Count - 1 do PSymbol(Reprs.Items↑[i])↑.Store(aText);
  end;
end;

```

741. Miscellaneous public-facing functions.

⟨Implementation for `dicthan.pas` 718⟩ +≡

```
function GetPrivateVoc(const fName: string): PVocabulary;
  var lName: string;
  begin lName ← fName;
  if ExtractFileExt(lName) = `` then lName ← lName + `.voc`;
  if  $\neg$ MFileExists(lName) then
    begin GetPrivateVoc ← nil; exit;
    end;
  GetPrivateVoc ← new(PVocabulary, ReadPrivateVoc(lName));
end;
```

742. Reading mml.vct entries. The `$MIZFILES/mml.vct` file contains all the vocabularies concatenated together into one giant vocabulary file. It uses lines prefixed with “#” followed by the article name to separate the vocabularies from different files. We search for the given article name (stored in the *fName* argument). When we find it, we construct the Vocabulary object (§738).

```
function GetPublicVoc (const fName: string; var fVocFile: text ) : PVocabulary;
  var lLine: string;
  begin GetPublicVoc ← nil; reset(fVocFile);
  while  $\neg$ eof(fVocFile) do
    begin readln(fVocFile, lLine);
    if (length(lLine) > 0) ∧ (lLine[1] = `#`) ∧ (copy(lLine, 2, length(lLine)) = fName) then
      begin GetPublicVoc ← new(PVocabulary, LoadVoc(fVocFile)); exit;
      end;
    end;
  end;
```

743. Reading from mml.vct. This function is used by `libtools/checkvoc.dpr` and in a couple user tools. In those other functions, they pass `$MIZFILES/mml.vct` as the value for *aFileName*. This procedure will then populate the *aMmlVcb* file associating to each article name its vocabulary.

```
procedure LoadMmlVcb (const aFileName: string; var aMmlVcb: MStringList ) ;
  var lFile: text; lDummy: char; lDictName: string; r: Integer;
  begin FileExam(aFileName); Assign(lFile, aFileName); Reset(lFile); { initialize file for reading }
  aMmlVcb.Init(1000); aMmlVcb.fSorted ← true;
  while  $\neg$ eof(lFile) do
    begin ReadLn(lFile, lDummy, lDictName);
    r ← aMmlVcb.AddObject(lDictName, new(PVocabulary, LoadVoc(lFile)));
    end;
  Close(lFile);
end;
```

744. Storing a vocabulary delegates much work (§740). However, since *fCount* is not initialized, I am uncertain how this works, exactly... Furthermore, this function is not used anywhere in Mizar.

```
procedure StoreMmlVcb(const aFileName: string; const aMmlVcb: MStringList);
  var lFile: text; i: Integer;
  begin Assign(lFile, aFileName); Rewrite(lFile);
  with aMmlVcb do
    for i ← 0 to fCount − 1 do PVocabulary(fList↑[i].fObject)↑.StoreVoc(fList↑[i].fString↑, lFile);
  Close(lFile);
end;
```

745. Like *StoreMmlVcb*, this function is not used anywhere in Mizar. This appears to produce the XML-equivalent to the previous function.

```
procedure StoreMmlVcbX(const aFileName: string; const aMmlVcb: MStringList);
  var i, s: Integer; c: char; VCXfile: XMLOutputStreamPtr;
  begin VCXfile ← new(XMLOutputStreamPtr, OpenFile(aFileName));
    VCXfile.Out_XElStart0(XMLElemName[elVocabularies]);
  with aMmlVcb do
    for i ← 0 to fCount − 1 do
      with PVocabulary(fList↑[i].fObject)↑ do
        begin VCXfile.Out_XElStart(XMLElemName[elVocabulary]);
          VCXfile.Out_XAttr(XMLAttrName[atName], fList↑[i].fString↑); VCXfile.Out_XAttrEnd;
          ⟨ Write vocabulary counts to XML file 746 ⟩;
          ⟨ Write symbols to vocabulary XML file 747 ⟩;
          VCXfile.Out_XElEnd(XMLElemName[elVocabulary]);
        end;
      VCXfile.Out_XElEnd(XMLElemName[elVocabularies]); dispose(VCXfile, Done);
    end;
```

746. We write out the counts of each kind of definition appearing in the article.

```
⟨ Write vocabulary counts to XML file 746 ⟩ ≡
  { Kinds }
  for c ← ‘A’ to ‘Z’ do
    if c ∈ AvailableSymbols then
      begin VCXfile.Out_XElStart(XMLElemName[elSymbolCount]);
        VCXfile.Out_XAttr(XMLAttrName[atKind], c);
        VCXfile.Out_XIntAttr(XMLAttrName[atNr], fSymbolCnt[c]); VCXfile.Out_XElEnd0;
      end
```

This code is used in section 745.

747. We write out each symbol appearing in the article’s vocabulary.

```
⟨ Write symbols to vocabulary XML file 747 ⟩ ≡
  { Symbols }
  VCXfile.Out_XElStart0(XMLElemName[elSymbols]);
  for s ← 0 to Reprs.Count − 1 do
    with PSymbol(Reprs.Items[s])↑ do
      begin VCXfile.Out_XElStart(XMLElemName[elSymbol]);
        VCXfile.Out_XAttr(XMLAttrName[atKind], Kind);
        VCXfile.Out_XAttr(XMLAttrName[atName], QuoteStrForXML(Repr));
        case Kind of
          ‘0’: VCXfile.Out_XIntAttr(XMLAttrName[atPriority], Prior);
          ‘R’: if Infinitive ≠ ‘’ then VCXfile.Out_XAttr(XMLAttrName[atInfinitive], Infinitive);
        end; VCXfile.Out_XElEnd0;
      end;
  VCXfile.Out_XElEnd(XMLElemName[elSymbols])
```

This code is used in section 745.

File 16

Scanner

748. The `scanner.pas` file contains the *MTokeniser* and the *MScanner*.

It is worth noting: if we want to extend Mizar to support Unicode, then we would want to hack this file accordingly. Or create a `utf8scanner` module, whichever. This scanner class is built specifically to work with ASCII characters, specifically accepting printable characters and the space (“ ”) characters as valid input.

```

<scanner.pas 748> ≡
  <GNU License 4>
unit scanner;
  interface ;
  uses errhan, mobjects;
  const MaxLineLength = 80;
    MaxConstInt = 2147483647; { = 231 - 1, maximal signed 32-bit integer }
  <Type declarations for scanner 749>
  implementation
  uses mizenv, librenv, mconsole, xml_dict, xml_inout;
  <Implementation for scanner.pas 750>
  end .

```

See also section 879.

749. Note that a *LexemRec* is really a standardized token. I was always raised to believe that a “lexeme” refers to the literal text underlying a token.

```

<Type declarations for scanner 749> ≡
type ASCIIArr = array [chr(0) .. chr(255)] of byte;
  LexemRec = record Kind: char;
    Nr: integer;
  end;
  <Token object class 751>;
  <Tokens collection class 753>;
  <MToken object class 761>;
  <MTokeniser class 764>;
  <MScanner object class 792>;

```

This code is used in section 748.

750. The “default allowed” characters are the 10 decimal digits, the 26 uppercase Latin letters, the 26 lowercase Latin letters, and the underscore (“_”) character.

⟨ Implementation for scanner.pas 750 ⟩ ≡
var *DefaultAllowed*: *AsciiArr* =
 (0,
 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 2, 2, 2, 2, 2, 2, 2, 2, 0, 0, 0, 0, 0, 0,
 0, 1, 0, 0, 0, 0, 1,
 { ‘_’ allowed in identifiers by default! }
 0, 1, 0, 0, 0, 0, 0,
 0,
 0,
 0,
 0,
 0, 0);

See also sections 752, 754, 755, 756, 759, 760, 762, 763, 765, 768, 769, 773, 788, 789, 791, 793, 802, 803, 804, 805, and 806.

This code is used in section 748.

751. Tokens object. A token contains a lexeme, but it extends an *MStr* object.

⟨ Token object class 751 ⟩ ≡
TokenPtr = ↑*TokenObj*;
TokenObj = **object** (*MStrObj*)
fLexem: *LexemRec*;
constructor *Init*(*aKind* : *char*; *aNr* : *integer* ; **const** *aSpelling*: *string*);
end

This code is used in section 749.

752. The constructor for a token requires its kind (functor, mode, predicate, etc.), and its internal “number”, as well as its raw lexeme *aSpelling*.

⟨ Implementation for scanner.pas 750 ⟩ +≡
constructor *TokenObj.Init*(*aKind* : *char*; *aNr* : *integer* ; **const** *aSpelling*: *string*);
begin *fLexem.Kind* ← *aKind*; *fLexem.Nr* ← *aNr*; *fStr* ← *aSpelling*;
end;

Section 16.1. COLLECTIONS OF TOKENS

753. We can populate a token collection from a dictionary file, or we can start with an empty collection. We can save our collection to a file. We can also insert (or “collect”) a new token into the collection.

⟨Tokens collection class 753⟩ ≡

```
TokensCollection = object (MSortedStrList)
  fFirstChar: array [chr(30) .. chr(255)] of integer;
  constructor InitTokens;
  constructor LoadDct(const aDctFileName: string);
  procedure SaveDct(const aDctFileName: string);
  procedure SaveXDct(const aDctFileName: string);
  function CollectToken(const aLexem: LexemRec; const aSpelling: string): boolean;
end
```

This code is used in section 749.

754. Construct empty token collection.

⟨Implementation for scanner.pas 750⟩ +≡

```
constructor TokensCollection.InitTokens;
  begin Init(100);
end;
```

755. Insert. If the collection already contains the token described by *aLexem*, then we just free up the memory allocated for the token (avoid duplicates). Otherwise, we insert the token.

⟨Implementation for scanner.pas 750⟩ +≡

```
function TokensCollection.CollectToken(const aLexem: LexemRec; const aSpelling: string): boolean;
  var k: integer; lToken: TokenPtr;
  begin lToken ← new(TokenPtr, Init(aLexem.Kind, aLexem.Nr, aSpelling));
  if Search(lToken, k) then { already contains token? }
    begin CollectToken ← false; dispose(lToken, Done)
    end
  else begin CollectToken ← true; Insert(lToken)
  end
end;
```

756. Load a dictionary. We open the dictionary “.dct” file (expects the file name to be lacking that extension), and construct an empty token collection. Then we iterate through the dictionary, reading each line, forming a new token, then inserting it into the collection.

The “.dct” file contains all the identifiers from articles referenced in the **environ** part of an article, and it will always have the first 148 lines be for reserved keywords. The format for a “.dct” file consists of lines of the form

$$\langle kind \rangle \langle number \rangle \sqcup \langle name \rangle$$

The “kind” is a single byte, the *number* is an integer assigned for the identifier, and *name* is the lexeme (string literal) for the identifier. This also has an XML file for this same information, the “.dcx” file.

⟨Implementation for scanner.pas 750⟩ +≡

```
constructor TokensCollection.LoadDct(const aDctFileName: string);
  var Dct: text; lKind, lDummy: AnsiChar; lNr: integer; lString: string; i: integer; c: char;
  begin assign(Dct, aDctFileName + ‘.dct’); reset(Dct); InitTokens;
  ⟨Load all tokens from the dictionary 757⟩;
  close(Dct); ⟨Index first character appearances among definitions 758⟩;
end;
```

757. We just iterate through the dictionary, constructing a new token for each line we read.

```

⟨Load all tokens from the dictionary 757⟩ ≡
  while ¬seekEof(Dct) do
    begin readln(Dct, lKind, lNr, lDummy, lString);
           Insert(new(TokenPtr, Init(char(lKind), lNr, lString)));
    end

```

This code is used in section 756.

758. We index the first appearance of each leading character in a token.

```

⟨Index first character appearances among definitions 758⟩ ≡
  for c ← chr(30) to chr(255) do fFirstChar[c] ← -1;
  for i ← 0 to Count - 1 do
    begin c ← TokenPtr(Items↑[fIndex↑[i]]↑.fStr[1];
           if fFirstChar[c] = -1 then fFirstChar[c] ← i;
    end

```

This code is used in section 756.

759. We save a token collection to a “.dct” file. This appears to just produce the concatenation of the definition kind, the identifier number, then a whitespace separating it from the lexeme. **Caution:** this is *not* an XML format! For that, see *SaveDctX*.

```

⟨Implementation for scanner.pas 750⟩ +≡
procedure TokensCollection.SaveDct(const aDctFileName: string);
  var i: integer; DctFile: text;
  begin assign(DctFile, aDctFileName + ‘.dct’); rewrite(DctFile);
  for i ← 0 to Count - 1 do
    with TokenPtr(Items↑[i])↑, fLexem do writeln(DctFile, AnsiChar(Kind), Nr, ‘ ’, fStr);
  close(DctFile);
end;

```

760. Save dictionary to XML file. The RNC (compact Relax NG Schema): Local dictionary for an article. The symbol kinds still use very internal notation.

```

elSymbols =
  attribute atAid {xsd:string}?,
  element elSymbols {
    element elSymbol {
      attribute atKind {xsd:string},
      attribute atNr {xsd:integer},
      attribute atName {xsd:integer}
    }*
  }

```

This creates the .dct file for an article.

⟨Implementation for scanner.pas 750⟩ +≡

```

procedure TokensCollection.SaveXDct(const aDctFileName: string);
var lEnvFile: XMLOutStreamObj; i: integer;
begin lEnvFile.OpenFile(aDctFileName);
with lEnvFile do
  begin Out_XElStart(XMLElemName[elSymbols]); Out_XAttr(XMLAttrName[atAid], ArticleID);
    Out_XQuotedAttr(XMLAttrName[atMizfiles], MizFiles);
    Out_XAttrEnd; { print elSymbols start-tag }
  for i ← 0 to Count − 1 do { print children elSymbol elements }
    with TokenPtr(Items↑[i])↑, fLexem do
      begin Out_XElStart(XMLElemName[elSymbol]);
        Out_XQuotedAttr(XMLAttrName[atKind], Kind); Out_XIntAttr(XMLAttrName[atNr], Nr);
        Out_XQuotedAttr(XMLAttrName[atName], fStr); Out_XElEnd0;
      end;
    Out_XElEnd(XMLElemName[elSymbols]); { print elSymbols end-tag }
  end;
lEnvFile.Done;
end;

```

Section 16.2. MIZAR TOKEN OBJECTS

761. This appears to be tokens for a specific file. An MToken extends a Token (§751).

```

⟨ MToken object class 761 ⟩ ≡
  MTokenPtr = ↑ MTokenObj;
  MTokenObj = object (TokenObj)
    fPos: Position;
    constructor Init(aKind : char; aNr : integer ; const aSpelling: string; const aPos: Position);
  end

```

This code is used in section 749.

762. Constructor. Construct a token. This might be a tad confusing, at least for me, because the lexeme is stored in the *fStr* field, whereas the standardized token is stored in the *fLexem* field.

We do not need to invoke the constructor for any ancestor class, because we just construct everything here. This seems like a bug waiting to happen. . .

```

⟨ Implementation for scanner.pas 750 ⟩ +≡
constructor MTokenObj.Init(aKind : char; aNr : integer;
  const aSpelling: string;
  const aPos: Position);
begin fLexem.Kind ← aKind; fLexem.Nr ← aNr; fStr ← aSpelling; fPos ← aPos;
end;

```

763. Token Kind constants. There are four kinds of tokens we want to distinguish: all valid tokens are either (1) numerals, or (2) identifiers. Then we also have (3) error tokens. But last, we have (4) end of text tokens.

These are for identifying everything which is neither an identifier defined in the vocabulary files, nor a reserved keyword.

```

⟨ Implementation for scanner.pas 750 ⟩ +≡
const Numeral = 'N'; Identifier = 'I'; ErrorSymbol = '?'; EOT = '!';

```

Section 16.3. TOKENISER

764. The first step in lexical analysis is to transform a character stream into a token stream. The Tokeniser extends the MToken object (§761), which in turn extends the Token object (§751).

In particular, we should take a moment to observe the new fields. The *fPhrase* field is a segment of the input stream which is expected to start at a non-whitespace character.

The *SliceIt* function populates the *TokensBuf* and the *fIdents* fields from the *fPhrase* field. I cannot find where *fTokens* is populated.

Note that the MTokeniser is not, itself, used anywhere *directly*. It's extended in the *MScannObj* class, which is used in `base/mscanner.pas` (and in `kernel/envhan.pas`).

The contract for *GetPhrase* ensures the *fPhrase* will be populated with a string ending with a space (“ ”) character or it will be the empty string. Any class extending *MTokeniser* must respect this contract.

⟨ MTokeniser class 764 ⟩ ≡

```

MTokeniser = object (MTokenObj)
  fPhrase: string;
  fPhrasePos: Position;
  fTokensBuf: MCollection;
  fTokens, fIdents: TokensCollection;
  constructor Init;
  destructor Done; virtual;
  procedure SliceIt; virtual;
  procedure GetToken; virtual;
  procedure GetPhrase; virtual;
  function EndOfText: boolean; virtual;
  function IsIdentifierLetter(ch : char): boolean; virtual;
  function IsIdentifierFirstLetter(ch : char): boolean; virtual;
  function Spelling(const aToken: LexemRec): string; virtual;
end

```

This code is used in section 749.

765. Spelling boils down to three cases (c.f., types of tokens §763): numerals, identifiers, and everything else. Numerals spell out the base-10 decimal expansion.

The other two cases boil down to finding the first matching token in the caller's collection of tokens with the same lexeme supplied as an argument, provided certain ‘consistency’ checks hold (the lexeme and token have the same *Kind*).

⟨ Implementation for scanner.pas 750 ⟩ +≡

```

function MTokeniser.Spelling(const aToken: LexemRec): string;
  var i: integer; s: string;
  begin Spelling ← ``;
  if aToken.Kind = Numeral then
    begin Str(aToken.Nr, s); Spelling ← s; end
  else if aToken.Kind = Identifier then ⟨ Spell an identifier for the MTokeniser 766 ⟩
    else ⟨ Spell an error or EOF for the MTokeniser 767 ⟩;
  end;

```

766. Spelling an identifier just needs to match the lexeme's number with the token's number. This finds the first matching token in the underlying collection, then terminates the function.

```

⟨ Spell an identifier for the MTokeniser 766 ⟩ ≡
  begin for  $i \leftarrow 0$  to  $fIdents.Count - 1$  do
    with  $TokenPtr(fIdents.Items \uparrow [i]) \uparrow$  do
      if  $fLexem.Nr = aToken.Nr$  then
        begin  $Spelling \leftarrow fStr$ ; exit
        end;
      end
    end
  end

```

This code is used in section 765.

767. Spelling anything else for the tokeniser needs the kind and number of the lexeme to match those of the token. Again, this finds the first matching token in the underlying collection, then terminates the function.

```

⟨ Spell an error or EOF for the MTokeniser 767 ⟩ ≡
  begin for  $i \leftarrow 0$  to  $fTokens.Count - 1$  do
    with  $TokenPtr(fTokens.Items \uparrow [i]) \uparrow$  do
      if  $(fLexem.Kind = aToken.Kind) \wedge (fLexem.Nr = aToken.Nr)$  then
        begin  $Spelling \leftarrow fStr$ ; exit
        end;
      end
    end
  end

```

This code is used in section 765.

768. Constructor. Initialising a tokeniser starts with a blank phrase and kind, with most fields set to zero.

```

⟨ Implementation for scanner.pas 750 ⟩ +≡
constructor MTokeniser.Init;
  begin  $fPos.Line \leftarrow 0$ ;  $fLexem.Kind \leftarrow \text{~}\sqcup\text{~}$ ;  $fPhrase \leftarrow \text{~}\sqcup\sqcup\text{~}$ ;  $fPhrasePos.Line \leftarrow 0$ ;
     $fPhrasePos.Col \leftarrow 0$ ;  $fTokensBuf.Init(80, 8)$ ;  $fTokens.Init(0)$ ;  $fIdents.Init(100)$ ;
  end;

```

769. Destructor. This chains to free up several fields, just invoking their destructors.

```

⟨ Implementation for scanner.pas 750 ⟩ +≡
destructor MTokeniser.Done;
  begin  $fPhrase \leftarrow \text{~}\text{~}$ ;  $fTokensBuf.Done$ ;  $fTokens.Done$ ;  $fIdents.Done$ ;
  end;

```

770. Aside on ASCII separators. Note: $\text{chr}(30)$ is the record separator in ASCII, and $\text{chr}(31)$ is the unit separator. Within a group (or table), the records are separated with the “RS” ($\text{chr}(30)$). As far as unit separators, Lammer Bies explains (lammertbies.nl/comm/info/ascii-characters):

The smallest data items to be stored in a database are called units in the ASCII definition. We would call them field now. The unit separator separates these fields in a serial data storage environment. Most current database implementations require that fields of most types have a fixed length. Enough space in the record is allocated to store the largest possible member of each field, even if this is not necessary in most cases. This costs a large amount of space in many situations. The US control code allows all fields to have a variable length. If data storage space is limited—as in the sixties—this is a good way to preserve valuable space. On the other hand is serial storage far less efficient than the table driven RAM and disk implementations of modern times. I can’t imagine a situation where modern SQL databases are run with the data stored on paper tape or magnetic reels...

We will introduce macros for the record separator and the unit separator, because Mizar’s front-end uses them specifically for the following purposes:

- (1) lines longer than 80 characters will contain a *record_separator* character (§797);
- (2) all other invalid characters are replaced with the *unit_separator* character (c.f., §798).

define *record_separator* $\equiv \text{chr}(30)$

define *unit_separator* $\equiv \text{chr}(31)$

771. Example of zeroeth step (“getting a phrase”) in tokenising. The *GetPhrase* function is left as an abstract method of the tokeniser, so it is worth discussing “What it is supposed to do” before getting to the tokenisation of strings.

Suppose we have the following snippet of Mizar:

```
begin

theorem
  for x being object
    holds x= x;
```

This is “sliced up” into the following “phrases” (drawn in boxes) which are clustered by lines:

```
begin_
theorem_
  for_ x_ being_ object_
  holds_ x=_ x;_
```

Observe that the “phrases” are demarcated by whitespaces (“_␣”) or linebreaks. This is the coarse “first pass” before we carve a “phrase” up into a token. A phrase contains at least one token, possibly multiple tokens (e.g., the phrase “ $x=_$ ” contains the two tokens “ x ” and “ $=$ ”).

What is the contract for a “phrase”? A phrase is *guaranteed* to either be equal to “_␣”, or it contains at least one token and it is *guaranteed* to end with a space “_␣” character (ASCII code #32). Further, there are no other possible “_␣” characters in a phrase *except* at the very end. A phrase is never an empty string.

The task is then to *slice up* each phrase into tokens.

772. Tokenise a phrase. When a “phrase” has been loaded into the tokeniser (which is an abstract method implemented by its descendent classes), we tokenise it — “slice it up” into tokens, thereby populating the *fTokensBuf* tokens buffer. This is invoked as needed by the *GetToken* method (§789).

This function is superficially complex, but upon closer scrutiny it is fairly straightforward.

Also note, despite being marked as “virtual”, this is not overridden anywhere in the Mizar program.

The contract ensures, barring catastrophe, the *fLexem*, *fStr*, and *fPos* be populated. **Importantly:** The *fLexem*’s token type is one of the four kinds given in the constant section (§763): **Numeral**, **Identifier**, **ErrorSymbol**, or **EOT**. What about the “reserved keywords” of Mizar? They are already present in the “.dct” file, which is loaded into the *fTokens* dictionary. So they will be discovered in step (§779) in this procedure.

```

⟨ Variables for slicing a phrase 772 ⟩ ≡
lCurrChar: integer; { index in fPhrase for current position }
EndOfSymbol: integer;
EndOfIdent: integer; { index in fPhrase for end of identifier }
FoundToken: TokenPtr; { most recently found token temporary variable }
lPos: Position; { position for debugging purposes }

```

See also sections 775, 778, 781, 783, and 785.

This code is used in section 773.

773. ⟨ Implementation for scanner.pas 750 ⟩ +≡

```

procedure MTokeniser.SliceIt;
  var ⟨ Variables for slicing a phrase 772 ⟩
  begin MizAssert(2333, fTokensBuf.Count = 0); { Requires: token buffer is empty }
  lCurrChar ← 1; lPos ← fPhrasePos;
  ⟨ Slice pragmas 774 ⟩;
  while fPhrase[lCurrChar] ≠ ‘␣’ do
    begin ⟨ Determine the ID 776 ⟩;
    ⟨ Try to find a dictionary symbol 779 ⟩;
    if EndOfSymbol < EndOfIdent then ⟨ Check identifier is not a number 782 ⟩;
    if FoundToken ≠ nil then
      with FoundToken↑ do
        begin lPos.Col ← fPhrasePos.Col + EndOfSymbol - 1;
        fTokensBuf.Insert(new(MTokenPtr, Init(fLexem.Kind, fLexem.Nr, fStr, lPos)));
        lCurrChar ← EndOfSymbol + 1; continue;
        end;
      { else FoundToken = nil }
      ⟨ Whoops! We found an unknown token, insert a 203 error token 787 ⟩;
    end;
  end;

```

774. We begin by slicing pragmas. This will insert the pragma into the tokens buffer.

Note that the “\$EOF” pragma indicates that we should treat the file as ending here. So we comply with the request, inserting the *EOT* (end of text) token as the next token to be offered to the user.

```

⟨ Slice pragmas 774 ⟩ ≡
if (lPos.Col = 1) ∧ (Pos(‘:’:$’, fPhrase) = 1) then
  begin fTokensBuf.Insert(new(MTokenPtr, Init(‘␣’, 0, copy(fPhrase, 3, length(fPhrase) - 3), lPos)));
  if copy(fPhrase, 1, 6) = ‘:’:$EOF’ then
    fTokensBuf.Insert(new(MTokenPtr, Init(EOT, 0, fPhrase, lPos)));
  exit
  end

```

This code is used in section 773.

775. We take the longest possible substring consisting of identifier characters as a possible identifier. The phrase is guaranteed to contain at least one token, maybe more, so we just keep going until we have exhausted the phrase or found a non-identifier character.

Note that all invalid characters are transformed into the “unit character” (c.f., §798). We should treat any occurrence of them as an error.

At the end of this stage of our tokenising journey, for valid tokens, we should have *EndOfIdent* and *IdentLength* both initialized here.

⟨ Variables for slicing a phrase 772 ⟩ +≡
IdentLength: integer;

776. ⟨ Determine the ID 776 ⟩ ≡
 { 1. attempt to determine the ID }
EndOfIdent ← *lCurrChar*;
if *IsIdentifierFirstLetter*(*fPhrase*[*EndOfIdent*]) **then**
 while (*EndOfIdent* < *length*(*fPhrase*)) ∧ *IsIdentifierLetter*(*fPhrase*[*EndOfIdent*]) **do**
 inc(*EndOfIdent*);
IdentLength ← *EndOfIdent* − *lCurrChar*;
if *fPhrase*[*EndOfIdent*] ≤ *unit_separator* **then**
 ⟨ Whoops! ID turns out to be invalid, insert an error token, then continue 777 ⟩;
 dec(*EndOfIdent*)

This code is used in section 773.

777. Recall (§797), we treat record separators as indicating the line is “too long” (i.e., more than 80 characters long). So we insert a 201 “Too long source line” error. But anything else is treated as an invalid identifier error.

⟨ Whoops! ID turns out to be invalid, insert an error token, then continue 777 ⟩ ≡
begin *lPos.Col* ← *fPhrasePos.Col* + *EndOfIdent* − 1;
if *fPhrase*[*EndOfIdent*] = *record_separator* **then**
 fTokensBuf.Insert(*new*(*MTokenPtr*, *Init*(*ErrorSymbol*, 200, ‘^’, *lPos*)))
else *fTokensBuf.Insert*(*new*(*MTokenPtr*, *Init*(*ErrorSymbol*, 201, ‘^’, *lPos*)));
 lCurrChar ← *EndOfIdent* + 1; *continue*;
end

This code is used in section 776.

778. We look at the current phrase and try to match against tokens found in the underlying dictionary. When we find a match, we check if there are *multiple* matches and return the last one (this reflects Mizar’s “the last version of the notation is preferred”). We implement this matching scheme using an infinite loop. Note that this uses a “**repeat...until false**” loop, which is identical to “**while true do begin ...end**” loop. (I am tempted to introduce a macro just to have this loop “**repeat...until end_of_time**”...)

Recall (§387), sorted lists have a field *fIndex* which is an array of indices (which are sorted while leaving the underlying array *Items* of data untouched).

Also, *lToken*, *lIndex* are used only in this code chunk. Here *lToken* is translated to an index of the underlying dictionary, so for clarity we introduce a macro to refer to the token directly. And *lIndex* is used as “the current character” index to compare the phrase to the token (indexed by *lToken*) as a match or not.

At the end of this chunk, if successful, then *FoundToken* will be set to a valid token pointer. Further, *EndOfPhrase* will be initialized.

A possible bug: what happens if we look through the entire phrase? We can’t “look any farther” down the phrase, so shouldn’t we throw an error? Or lazily read more characters? Or...something?

Never fear: this will never happen with Mizar’s grammar. The “reserved words” are *always* separated from the other stuff by at least one whitespace.

Also we note the list of symbols is sorted lexicographically.

This appears to match the phrase with the longest possible matching entry in the list of symbols (it is “maximal munch”).

```
define the_item(#) ≡ Items↑[fIndex↑[#]]
define the_token(#) ≡ TokenPtr(the_item(#))↑
```

⟨ Variables for slicing a phrase 772 ⟩ +≡

EndOfPhrase: integer; { index in *fPhrase* for candidate token }

lIndex: integer; { index for *fIndex* entry }

lToken: integer; { index for entries in dictionary starting with the first character of the current token }

779. Reserved keywords and defined terms are loaded into the *fTokens* dictionary.

⟨ Try to find a dictionary symbol 779 ⟩ ≡

```
EndOfPhrase ← lCurrChar; FoundToken ← nil; EndOfSymbol ← EndOfPhrase − 1;
```

```
{ initialized for comparison }
```

```
lToken ← fTokens.fFirstChar[fPhrase[EndOfPhrase]]; inc(EndOfPhrase);
```

```
if (lToken ≥ 0) then
```

```
  with fTokens do
```

```
    begin lIndex ← 2;
```

```
    repeat { infinite loop }
```

```
      ⟨ If we matched a dictionary entry, then initialize FoundToken 780 ⟩;
```

```
      if fPhrase[EndOfPhrase] = ‘␣’ then break; { we are done! }
```

```
      if (lIndex ≤ length(the_token(lToken).fStr)) ∧
```

```
        (the_token(lToken).fStr[lIndex] = fPhrase[EndOfPhrase]) then
```

```
        begin inc(lIndex); inc(EndOfPhrase) end { iterate, look at next character }
```

```
      else if (lToken < Count − 1) then { try looking for the last matching item }
```

```
        begin if (copy(the_token(lToken).fStr, 1, lIndex − 1) =
```

```
          copy(the_token(lToken + 1).fStr, 1, lIndex − 1)) then inc(lToken) { iterate }
```

```
        else break; { we are done! }
```

```
      end
```

```
      else break; { we are done! }
```

```
    until false;
```

```
  end
```

This code is used in section 773.

780. If we have *lIndex* (the index of the current phrase) be longer than the lexeme of the current dictionary entry's lexeme, then we should populate *FoundItem*.

```

⟨ If we matched a dictionary entry, then initialize FoundToken 780 ⟩ ≡
  if lIndex > length(the_token(lToken).fStr) then { we matched the token }
    begin FoundToken ← the_item(lToken); EndOfSymbol ← EndOfPhrase − 1;
    end

```

This code is used in section 779.

781. When the identifier is not a number, we insert an “identifier” token into the tokens buffer.

```

⟨ Variables for slicing a phrase 772 ⟩ +≡
lFailed: integer; { index of first non-digit character }
I: integer; { index ranging over the raw lexeme string }
lSpelling: string; { raw lexeme as a string }

```

```

782. ⟨ Check identifier is not a number 782 ⟩ ≡
  begin lSpelling ← copy(fPhrase, lCurrChar, IdentLength);
  lPos.Col ← fPhrasePos.Col + EndOfIdent − 1;
  if (ord(fPhrase[lCurrChar]) > ord(‘0’)) ∧ (ord(fPhrase[lCurrChar]) ≤ ord(‘9’)) then
    begin lFailed ← 0; { location of non-digit character }
    for I ← 1 to IdentLength − 1 do
      if (ord(fPhrase[lCurrChar + I]) < ord(‘0’)) ∨ (ord(fPhrase[lCurrChar + I]) > ord(‘9’)) then
        begin lFailed ← I + 1; break;
        end;
      if lFailed = 0 then { if all characters are digits }
        ⟨ Whoops! Identifier turned out to be a number! 786 ⟩;
      end;
    ⟨ Add token to tokens buffer and iterate 784 ⟩;
  end

```

This code is used in section 773.

783. We add an *Identifier* token to the tokens buffer.

```

⟨ Variables for slicing a phrase 772 ⟩ +≡
lIdent: TokenPtr;

```

```

784. ⟨ Add token to tokens buffer and iterate 784 ⟩ ≡
  lIdent ← new(TokenPtr, Init(Identifier, fIdents.Count + 1, lSpelling));
  if fIdents.Search(lIdent, I) then dispose(lIdent, Done)
  else fIdents.Insert(lIdent);
  fTokensBuf.Insert(new(MTokenPtr, Init(Identifier, TokenPtr(fIdents.Items↑[I])↑.fLexem.Nr, lSpelling,
    lPos)));
  lCurrChar ← EndOfIdent + 1; continue

```

This code is used in section 782.

785. If we goofed and all the characters turned out to be digits (i.e., the identifier *was* a numeral after all), we should clean things up here. Observe we will end up *continue*-ing along the loop.

When the numeral token is larger than $MaxConstInt = 2^{31} - 1$ (the largest 32-bit integer, §748), then we should raise a “Too large numeral” 202 error token. If we wanted to support “arbitrary precision” numbers, then this should be modified.

We can either insert into the tokens buffer an error token (in two possible outcomes) or a numeral token (in the third possible outcome).

⟨ Variables for slicing a phrase 772 ⟩ +≡
lNumber: *longint*;
J: *integer*;

786. ⟨ Whoops! Identifier turned out to be a number! 786 ⟩ ≡
begin if *IdentLength* > *length(IntToStr(MaxConstInt))* **then** { insert error token }
 begin *fTokensBuf.Insert(new(MTokenPtr, Init(ErrorSymbol, 202, lSpelling, lPos)))*;
 lCurrChar ← *EndOfIdent* + 1; *continue*;
 end;
lNumber ← 0; *J* ← 1;
for *I* ← *IdentLength* − 1 **downto** 0 **do**
 begin *lNumber* ← *lNumber* + (*ord(fPhrase[lCurrChar + I])* − *ord('0')*) * *J*; *J* ← *J* * 10;
 end;
if *lNumber* > *MaxConstInt* **then** { insert error token }
 begin *fTokensBuf.Insert(new(MTokenPtr, Init(ErrorSymbol, 202, lSpelling, lPos)))*;
 lCurrChar ← *EndOfIdent* + 1; *continue*;
 end; { insert numeral token }
 fTokensBuf.Insert(new(MTokenPtr, Init(Numeral, lNumber, lSpelling, lPos)));
 lCurrChar ← *EndOfIdent* + 1; *continue*;
end

This code is used in section 782.

787. If we have tokenised the phrase, but the token is not contained in the dictionary, then we should raise a 203 error.

⟨ Whoops! We found an unknown token, insert a 203 error token 787 ⟩ ≡
 lPos.Col ← *fPhrasePos.Col* + *lCurrChar* − 1;
 fTokensBuf.Insert(new(MTokenPtr, Init(ErrorSymbol, 203, fPhrase[lCurrChar], lPos))); *inc(lCurrChar)*

This code is used in section 773.

788. We have purely abstract methods which will invoke *Abstract1* (§308), which raises a runtime error.

⟨ Implementation for scanner.pas 750 ⟩ +≡
procedure *MTokeniser.GetPhrase*;
 begin *Abstract1*;
 end;
function *MTokeniser.EndOfText*: *boolean*;
 begin *Abstract1*; *EndOfText* ← *false*;
 end;
function *MTokeniser.IsIdentifierLetter*(*ch* : *char*): *boolean*;
 begin *Abstract1*; *IsIdentifierLetter* ← *false*;
 end;

789. Get a token. Getting a token from the tokeniser will check if we’ve exhausted the input stream (which tests if the kind of *fLexem* is *EOT*), and exit if we have.

Otherwise, it looks to see if we’ve got tokens left in the buffer. If so, just pop one and exit.

But when the token buffer is empty, we invoke the abstract method *GetPhrase* to read some of the input stream. If it turns out there’s nothing left to read, then update the tokeniser to be in the “end of text” state.

When we have some of the input stream read into the *fPhrase* field, we tokenise it using the *SliceIt* function. Then we pop a token from the buffer of tokens.

This will populate *fLexem*, *fStr*, and *fPos* with the new token, lexeme, and position...but that’s only because *GetPhrase* (§793) and *SliceIt* (§772) do the actual work.

⟨Implementation for scanner.pas 750⟩ +≡

```
procedure MTokeniser.GetToken;
begin if fLexem.Kind = EOT then exit;
if fTokensBuf.Count > 0 then
  begin ⟨Pop a token from the underlying tokens stack 790⟩;
  exit;
  end;
  GetPhrase;
if EndOfText then
  begin fLexem.Kind ← EOT; fStr ← ‘ ’; fPos ← fPhrasePos; inc(fPos.Col);
  exit;
  end;
  SliceIt; ⟨Pop a token from the underlying tokens stack 790⟩;
end;
```

790. Popping a token will update the lexeme, str, and position fields to be populated from the first item in the tokens buffer. Then it will free that item from the tokens buffer, shifting everything down by one.

⟨Pop a token from the underlying tokens stack 790⟩ ≡

```
fLexem ← MTokenPtr(fTokensBuf.Items↑[0])↑.fLexem;
fStr ← MTokenPtr(fTokensBuf.Items↑[0])↑.fStr; fPos ← MTokenPtr(fTokensBuf.Items↑[0])↑.fPos;
fTokensBuf.AtFree(0)
```

This code is used in sections 789 and 789.

791. Testing if the given character is an identifier character or not requires invoking the abstract method *IsIdentifierLetter* (§788).

⟨Implementation for scanner.pas 750⟩ +≡

```
function MTokeniser.IsIdentifierFirstLetter(ch : char): boolean;
begin IsIdentifierFirstLetter ← IsIdentifierLetter(ch);
end;
```

Section 16.4. SCANNER OBJECT

792. This extends the Tokeniser class (§764). It is the only class extending the Tokeniser class.

⟨MScanner object class 792⟩ ≡

```

MScannPtr = ↑MScannObj;
MScannObj = object (MTokeniser)
  Allowed: ASCIIArr;
  fSourceBuff: pointer;
  fSourceBuffSize: word;
  fSourceFile: text;
  fCurrentLine: string;
  constructor InitScanning(const aFileName, aDctFileName: string);
  destructor Done; virtual;
  procedure GetPhrase; virtual;
  procedure ProcessComment(fLine, fStart: integer; cmt: string); virtual;
  function EndOfText: boolean; virtual;
  function IsIdentifierLetter(ch: char): boolean; virtual;
end

```

This code is used in section 749.

793. Get a phrase. We search through the lines for the “first phrase” (i.e., first non-whitespace character, which indicates the start of something interesting). Comments are thrown away as are Mizar pragmas.

This will update *fCurrentLine* as needed, setting it to the next line in the input stream buffer. It will assign a *copy* of the phrase to the field *fPhrase*, as well as update the *fPhrasePos*.

There is a comment in Polish, “uzyskanie pierwszego znaczącego znaku”, which Google translates as: “obtaining the first significant sign”. This seemed like a natural “chunk” of code to study in isolation.

The contract for *GetPhrase* ensures the *fPhrase* will be populated with a string ending with a space (“`␣`”) character, or it will be the empty string (when the end of text has been encountered).

⟨Implementation for scanner.pas 750⟩ +≡

```

procedure MScannObj.GetPhrase;
  const Prohibited: ASCIIArr = ⟨Characters prohibited by MScanner 794⟩;
  var i, k: integer;
  begin fPhrasePos.Col ← fPhrasePos.Col + length(fPhrase) - 1;
  ⟨Find the first significant ‘sign’ 795⟩;
  for i ← fPhrasePos.Col to length(fCurrentLine) do
    if fCurrentLine[i] = ‘␣’ then break;
  fPhrase ← Copy(fCurrentLine, fPhrasePos.Col, i - fPhrasePos.Col + 1);
  end;

```

794. The prohibited ASCII characters are everything *NOT* among the follow characters:

```

␣ ! " # $ % & ' ( ) * + , - . / : ; < = > ? @
[ \ ] ^ _ ` { | } ~ 0 1 2 3 4 5 6 7 8 9
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
a b c d e f g h i j k l m n o p q r s t u v w x y z

```

The reader will observe these are all the “graphic” ASCII characters, plus the space (“␣”) character.

```

⟨ Characters prohibited by MScanner 794 ⟩ ≡
(1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,
0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1,
1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1)

```

This code is used in section 793.

795. Note that the *fCurrentLine* will end with a whitespace, when we have not consumed the entire underlying input stream.

```

⟨ Find the first significant ‘sign’ 795 ⟩ ≡
  while fCurrentLine[fPhrasePos.Col] = “␣” do
    begin if fPhrasePos.Col ≥ length(fCurrentLine) then ⟨ Populate the current line 796 ⟩;
      inc(fPhrasePos.Col);
    end

```

This code is used in section 793.

796. Now, populating the current line requires a bit of work. We ensure the end of the current line will end with a space character (“␣”), which will guarantee the loop iteratively consumes all empty lines in the file.

Once we arrive at a non-space character, we will break the loop containing this chunk of code. If we have exhausted the underlying input stream, then we will have *EndOfText* be true. Should that occur, we exit the function.

```

⟨ Populate the current line 796 ⟩ ≡
  begin if EndOfText then exit;
    inc(fPos.Line); inc(fPhrasePos.Line); readln(fSourceFile, fCurrentLine);
    ⟨ Scan for pragmas, and exit if we found one 800 ⟩;
    ⟨ Skip comments 801 ⟩;
    ⟨ Trim whitespace from the right of the current line 799 ⟩;
    ⟨ Replace every invalid character in current line with the unit character 798 ⟩;
    fCurrentLine ← fCurrentLine + “␣”;
    if ¬LongLines then
      if length(fCurrentLine) > MaxLineLength then ⟨ Replace end of long line with record separator 797 ⟩;
      { Assert: we have fCurrentLine end in “␣” }
      fPhrasePos.Col ← 0; fPos.Col ← 0;
    end

```

This code is used in section 795.

797. When we have excessively long lines, and we have not enabled “long line mode”, then we just delete everything after $MaxLineLength + 1$ and set $MaxLineLength - 1$ to the record separator (which is rejected by the Mizar lexer) and the last character in the line to the space character.

⟨ Replace end of long line with record separator 797 ⟩ \equiv
begin *delete*(*fCurrentLine*, $MaxLineLength + 1$, $length(fCurrentLine)$);
fCurrentLine[$MaxLineLength - 1$] \leftarrow *record_separator*;
fCurrentLine[$MaxLineLength$] \leftarrow ‘ \sqcup ’;
end

This code is used in section 796.

798. In particular, if we every encounter an “invalid” character, then we just replace it with the “unit separator” character.

⟨ Replace every invalid character in current line with the unit character 798 ⟩ \equiv
for $k \leftarrow 1$ **to** $length(fCurrentLine) - 1$ **do**
 if *Prohibited*[*fCurrentLine*[k]] > 0 **then** *fCurrentLine*[k] \leftarrow *unit_separator*

This code is used in section 796.

799. We will trim whitespace from the right of the current line at least twice.

⟨ Trim whitespace from the right of the current line 799 ⟩ \equiv
 $k \leftarrow length(fCurrentLine)$;
while ($k > 0$) \wedge (*fCurrentLine*[k] = ‘ \sqcup ’) **do** *dec*(k);
 delete(*fCurrentLine*, $k + 1$, $length(fCurrentLine)$)

This code is used in sections 796 and 800.

800. Pragmas in Mizar are special comments which start a line with “ $::\$$ ”. They are useful for naming theorems (“ $::\$N \langle name \rangle$ ”), or toggling certain phases of the Mizar checker. This will process the comment (§802).

Since pragmas are important, we treat it as a token (and not a comment to be thrown away).

Note: if you try to invoke a pragma, but do not place it at the start of a line, then Mizar will treat it like a comment.

⟨ Scan for pragmas, and exit if we found one 800 ⟩ \equiv
 $k \leftarrow Pos('::\$ ', fCurrentLine)$; { Preprocessing directive }
if ($k = 1$) **then**
 begin *ProcessComment*(*fPhrasePos.Line*, 1, *copy*(*fCurrentLine*, 1, $length(fCurrentLine)$));
 ⟨ Trim whitespace from the right of the current line 799 ⟩;
 fCurrentLine \leftarrow *fCurrentLine* + ‘ \sqcup ’; *fPhrase* \leftarrow *Copy*(*fCurrentLine*, 1, $length(fCurrentLine)$);
 fPhrasePos.Col \leftarrow 1; *fPos.Col* \leftarrow 0; *exit*
 end

This code is used in section 796.

801. Scanning a comment will effectively replace the start of the comment (“ $::$ ”) up to and including the end of the line, with a single space. This will process the comment (§802).

⟨ Skip comments 801 ⟩ \equiv
 $k \leftarrow Pos(':: ', fCurrentLine)$; { Comment }
if ($k \neq 0$) **then**
 begin *ProcessComment*(*fPhrasePos.Line*, k , *copy*(*fCurrentLine*, k , $length(fCurrentLine)$));
 delete(*fCurrentLine*, $k + 1$, $length(fCurrentLine)$); *fCurrentLine*[k] \leftarrow ‘ \sqcup ’;
 end

This code is used in section 796.

802. “Processing a comment” really means skipping the comment.

⟨Implementation for scanner.pas 750⟩ +≡

```
procedure MScannObj.ProcessComment(fLine, fStart : integer; cmt : string);
begin end;
```

803. Testing if the scanner has exhausted the input stream amounts to checking the current line has been completely read *and* the current source file has arrived at an *texttfeof* state.

⟨Implementation for scanner.pas 750⟩ +≡

```
function MScannObj.EndOfText: boolean;
begin EndOfText ← (fPhrasePos.Col ≥ length(fCurrentLine)) ∧ eof(fSourceFile);
end;
```

804. Testing if a character is an identifier letter amounts to testing if it is allowed (i.e., not disallowed).

⟨Implementation for scanner.pas 750⟩ +≡

```
function MScannObj.IsIdentifierLetter(ch : char): boolean;
begin IsIdentifierLetter ← Allowed[ch] ≠ 0;
end;
```

805. Constructor. The only way to construct a scanner. This expects an article to be read in *aFileName* and a dictionary to be loaded (*aDctFileName*, loaded with §756). The buffer size for reading *aFileName* is initially #4000.

CAUTION: This will cause a memory leak if you try to do unit testing with the parser. Specifically the *loadDct* method appears to allocate memory which is never freed adequately. I worry this might be symptomatic of a larger problem.

⟨Implementation for scanner.pas 750⟩ +≡

```
constructor MScannObj.InitScanning(const aFileName, aDctFileName: string);
begin inherited Init; Allowed ← DefaultAllowed; fTokens.LoadDct(aDctFileName); { memory leaked }
assign(fSourceFile, aFileName); fSourceBuffSize ← #4000; getmem(fSourceBuff, fSourceBuffSize);
settextbuf(fSourceFile, fSourceBuff↑, #4000); reset(fSourceFile); fCurrentLine ← ‘ ’; GetToken;
end;
```

806. Destructor. We must remember to close the source file, free the buffer, close the lights, and lock the doors.

⟨Implementation for scanner.pas 750⟩ +≡

```
destructor MScannObj.Done;
begin close(fSourceFile); FreeMem(fSourceBuff, fSourceBuffSize); fCurrentLine ← ‘ ’; inherited Done;
end;
```

File 17

Format

807. The first step towards disambiguating the meaning of identifiers is to use “formats”. Recall from, e.g., Andrzej Trybulec’s “Some Features of the Mizar Language” (ESPRIT Workshop, Torino, 1993; mizar.uwb.edu.pl/project/t §3) that the “Format” describes with how many arguments a “Constructor Symbol” may be used. The basic formats:

- Predicates $\langle \text{lexeme}, \text{left arguments number}, \text{right arguments number} \rangle$
- Modes $\langle \text{lexeme}, \text{arguments number} \rangle$ for “mode Foo of T_1, \dots, T_n ” where n is the arguments number
- Functors $\langle \text{lexeme}, \text{left arguments number}, \text{right arguments number} \rangle$
- Bracket functors $\langle \text{left bracket lexeme}, \text{arguments number}, \text{right bracket lexeme} \rangle$
- Selector $\langle \text{lexeme}, 1 \rangle$
- Structure $\langle \text{lexeme}, \text{arguments number} \rangle$ for generic structures over $[\text{arguments number}]$ parameters
- Structure $\langle \text{lexeme}, 1 \rangle$ for situations where we write “the [structure] of [term]”

We store these format information in XML files. See also Adam Grabowski, Artur Korniłowicz, and Adam Naumowicz’s “Mizar in a Nutshell” (viz. §2.3, [doi:10.6092/issn.1972-5787/1980](https://doi.org/10.6092/issn.1972-5787/1980)) for a little more discussion about formats.

```

<_format.pas 807> ≡
  <GNU License 4>
unit _formats;
interface
  uses mobjects, scanner, dictan, xml_inout;
  <Declare classes for _formats.pas 809>
  function CompareFormats(aItem1, aItem2 : Pointer): Integer;
  function In_Format(fInFile : XMLInStreamPtr): MFormatPtr;
  <Global variables (_formats.pas) 808>
implementation
  uses errhan, xml_dict, xml_parser
  mdebug , info end_mdebug;
  <Implementation for _formats.pas 810>
end .

```

808.

```

<Global variables (_formats.pas) 808> ≡
var gFormatsColl: MFormatsList; gPriority: BinIntFunc; gFormatsBase: integer;

```

This code is used in section 807.

809. Broadly speaking, there are only 3 types of “formats”: prefix formats, infix formats, bracket-like formats. These are viewed as “subclasses” of a base *MFormat* object.

We will want to collect the formats from articles referenced by the environment of an article being verified or parsed. This motivates the *MFormatList* object.

```

⟨ Declare classes for _formats.pas 809 ⟩ ≡
  ⟨ Declare MFormat object 811 ⟩;
  { TODO: add assertions that nr. of all format arguments is equal to the number of visible args
    (Visible) of a pattern }
  ⟨ Declare MPrefixFormat object 813 ⟩;
  ⟨ Declare MInfixFormat object 815 ⟩;
  ⟨ Declare MBracketFormat object 817 ⟩;
  ⟨ Declare MFormatsList object 825 ⟩;

```

This code is used in section 807.

810. The *presentation* of the code is a bit disorganized from the perspective of pedagogy, so I am going to re-organize for the sake of discussing it.

```

⟨ Implementation for _formats.pas 810 ⟩ ≡
  ⟨ Constructors for derived format classess 812 ⟩
  ⟨ Compare formats 819 ⟩
  ⟨ Implementation for MFormatsList 826 ⟩
  ⟨ Read formats from an XML input stream 837 ⟩
  ⟨ Implement MFormatObj 838 ⟩

```

This code is used in section 807.

811. Format base class. All format instances have a lexeme called its *fSymbol*. Recall that *LexemeRec* (§749) is a normalized token using a single character to describe its kind, and an integer to keep track of it (instead of relying on a raw string).

```

⟨ Declare MFormat object 811 ⟩ ≡
  MFormatPtr = ↑MFormatObj;
  MFormatObj = object (MObject)
    fSymbol: LexemeRec;
    constructor Init(aKind : Char; aSymNr : integer);
    procedure Out_Format(var fOutFile : XMLOutputStreamObj; aFormNr : integer);
  end

```

This code is used in section 809.

812. The constructor expects the “kind” of the object and its symbol number.

```

⟨ Constructors for derived format classess 812 ⟩ ≡
constructor MFormatObj.Init(aKind : Char; aSymNr : integer);
  begin fSymbol.Kind ← aKind; fSymbol.Nr ← aSymNr;
  end;

```

See also sections 814, 816, and 818.

This code is used in section 810.

813. Prefix format object.

```

⟨ Declare MPrefixFormat object 813 ⟩ ≡
  MPrefixFormatPtr = ↑MPrefixFormatObj;
  MPrefixFormatObj = object (MFormatObj)
    fRightArgsNbr: byte;
    constructor Init(aKind : Char; aSymNr, aRArgsNbr : integer);
  end

```

This code is used in section 809.

814. Prefix formats track how many arguments are to the right of the prefix symbol.

```

⟨ Constructors for derived format classes 812 ⟩ +≡
constructor MPrefixFormatObj.Init(aKind : Char; aSymNr, aRArgsNbr : integer);
  begin fSymbol.Kind ← aKind; fSymbol.Nr ← aSymNr; fRightArgsNbr ← aRArgsNbr;
  end;

```

815. Infix format object.

```

⟨ Declare MInfixFormat object 815 ⟩ ≡
  MInfixFormatPtr = ↑MInfixFormatObj;
  MInfixFormatObj = object (MPrefixFormatObj)
    fLeftArgsNbr: byte;
    constructor Init(aKind : Char; aSymNr, aLArgsNbr, aRArgsNbr : integer);
  end

```

This code is used in section 809.

816. And just as prefix symbols tracks the number of arguments to the right, infix symbols tracks the number of arguments to both the left and right.

```

⟨ Constructors for derived format classes 812 ⟩ +≡
constructor MInfixFormatObj.Init(aKind : Char; aSymNr, aLArgsNbr, aRArgsNbr : integer);
  begin fSymbol.Kind ← aKind; fSymbol.Nr ← aSymNr; fLeftArgsNbr ← aLArgsNbr;
  fRightArgsNbr ← aRArgsNbr;
  end;

```

817. Bracket format object.

```

⟨ Declare MBracketFormat object 817 ⟩ ≡
  MBracketFormatPtr = ↑MBracketFormatObj;
  MBracketFormatObj = object (MInfixFormatObj)
    fRightSymbolNr: integer;
    fArgsNbr: byte;
    constructor Init(aLSymNr, aRSymNr, aArgsNbr, aLArgsNbr, aRArgsNbr : integer);
  end

```

This code is used in section 809.

818. ⟨ Constructors for derived format classes 812 ⟩ +≡

```

constructor MBracketFormatObj.Init(aLSymNr, aRSymNr, aArgsNbr, aLArgsNbr, aRArgsNbr : integer);
  begin fSymbol.Kind ← 'K'; fSymbol.Nr ← aLSymNr; fRightSymbolNr ← aRSymNr;
  fArgsNbr ← aArgsNbr; fLeftArgsNbr ← aLArgsNbr; fRightArgsNbr ← aRArgsNbr;
  end;

```

819. Ordering format objects. We need a *Compare* ordering function on formats. This is a lexicographic ordering on the (kind, number of right symbols, number of arguments, number of left symbols), more or less.

```

⟨ Compare formats 819 ⟩ ≡
function CompareFormats(aItem1, aItem2 : Pointer): Integer;
  begin CompareFormats ← 1;
  if MFormatPtr(aItem1)↑.fSymbol.Kind < MFormatPtr(aItem2)↑.fSymbol.Kind then
    CompareFormats ← -1
  else if MFormatPtr(aItem1)↑.fSymbol.Kind = MFormatPtr(aItem2)↑.fSymbol.Kind then
    ⟨ Compare symbols of the same kind 820 ⟩;
  end;

```

This code is used in section 810.

820. We then check the indexing number of the symbol. When they are the same, we look at the next “entry” in the tuple.

```

⟨ Compare symbols of the same kind 820 ⟩ ≡
  if MFormatPtr(aItem1)↑.fSymbol.Nr < MFormatPtr(aItem2)↑.fSymbol.Nr then
    CompareFormats ← -1
  else if MFormatPtr(aItem1)↑.fSymbol.Nr = MFormatPtr(aItem2)↑.fSymbol.Nr then
    ⟨ Compare same kinded symbols with the same number 821 ⟩

```

This code is used in section 819.

821. The next “entry” in the tuple depends on the kind of symbols we are comparing. Selectors (‘U’) are, at this point, identical (so we return zero). Note that ‘J’ is a historic artifact no longer used (in fact, I cannot locate its meaning in the literature I possess).

Structure (‘G’), right functor brackets (‘L’), modes (‘M’), and attributes (‘V’) can be compared as prefix symbols.

Functors (‘O’) and predicates (‘R’) can be compared as infix symbols.

Left functor brackets (‘K’) can be compared first with bracket-specific characteristics, then as infix symbols.

```

⟨ Compare same kinded symbols with the same number 821 ⟩ ≡
  case MFormatPtr(aItem1)↑.fSymbol.Kind of
    ‘J’, ‘U’: CompareFormats ← 0;
    ‘G’, ‘L’, ‘M’, ‘V’: ⟨ Compare prefix symbols 822 ⟩;
    ‘O’, ‘R’: ⟨ Compare infix symbols 824 ⟩;
    ‘K’: ⟨ Compare bracket symbols 823 ⟩;
  endcases

```

This code is used in section 820.

822. Comparing prefixing symbols, at this points, can only compare the number of arguments to the right.

```

⟨ Compare prefix symbols 822 ⟩ ≡
  if MPrefixFormatPtr(aItem1)↑.fRightArgsNbr < MPrefixFormatPtr(aItem2)↑.fRightArgsNbr then
    CompareFormats ← -1
  else if MPrefixFormatPtr(aItem1)↑.fRightArgsNbr = MPrefixFormatPtr(aItem2)↑.fRightArgsNbr then
    CompareFormats ← 0

```

This code is used in section 821.

823. Comparing bracket symbols first tries to compare the number of symbols to its right. If these are equal, then we try to compare the number of arguments. If these are equal, then we compare them “as if” they were infixing symbols.

```

⟨ Compare bracket symbols 823 ⟩ ≡
  if MBracketFormatPtr(aItem1)↑.fRightSymbolNr < MBracketFormatPtr(aItem2)↑.fRightSymbolNr
    then CompareFormats ← -1
  else if MBracketFormatPtr(aItem1)↑.fRightSymbolNr = MBracketFormatPtr(aItem2)↑.fRightSymbolNr
    then
      if MBracketFormatPtr(aItem1)↑.fArgsNbr < MBracketFormatPtr(aItem2)↑.fArgsNbr then
        CompareFormats ← -1
      else if MBracketFormatPtr(aItem1)↑.fArgsNbr = MBracketFormatPtr(aItem2)↑.fArgsNbr then
        ⟨ Compare infix symbols 824 ⟩

```

This code is used in section 821.

824. Comparing infixing symbols compares the number of arguments to the left. If these are equal, then we try to compare the number of arguments to the right. If these are equal, then we return 0.

```

⟨ Compare infix symbols 824 ⟩ ≡
  if MInfixFormatPtr(aItem1)↑.fLeftArgsNbr < MInfixFormatPtr(aItem2)↑.fLeftArgsNbr then
    CompareFormats ← -1
  else if MInfixFormatPtr(aItem1)↑.fLeftArgsNbr = MInfixFormatPtr(aItem2)↑.fLeftArgsNbr then
    if MInfixFormatPtr(aItem1)↑.fRightArgsNbr < MInfixFormatPtr(aItem2)↑.fRightArgsNbr then
      CompareFormats ← -1
    else if MInfixFormatPtr(aItem1)↑.fRightArgsNbr = MInfixFormatPtr(aItem2)↑.fRightArgsNbr
      then CompareFormats ← 0

```

This code is used in sections 821 and 823.

Section 17.1. LIST OF FORMATS

825. We have a collection of format objects managed by a *MFormatsList* object. There are two groups of public functions: “Lookup” functions (to find the format matching certain parameters), and “Collect” functions (to insert a new format).

```

⟨ Declare MFormatsList object 825 ⟩ ≡
  MFormatsListPtr = ↑MFormatsList;
  MFormatsList = object (MSortedList)
    constructor Init (ALimit : Integer);
    constructor LoadFormats (fName : string);
    procedure StoreFormats (fName : string);
    function Lookup_PrefixFormat (aKind : char; aSymNr, aArgsNbr : integer): integer;
    function Lookup_FuncFormat (aSymNr, aLArgsNbr, aRArgsNbr : integer): integer;
    function Lookup_BracketFormat (aLSymNr, aRSymNr, aArgsNbr, aLArgsNbr, aRArgsNbr : integer):
      integer;
    function Lookup_PredFormat (aSymNr, aLArgsNbr, aRArgsNbr : integer): integer;
    function CollectFormat (aFormat : MFormatPtr): integer;
    function CollectPrefixForm (aKind : char; aSymNr, aArgsNbr : integer): integer;
    function CollectFuncForm (aSymNr, aLArgsNbr, aRArgsNbr : integer): integer;
    function CollectBracketForm (aLSymNr, aRSymNr, aArgsNbr, aLArgsNbr, aRArgsNbr : integer):
      integer;
    function CollectPredForm (aSymNr, aLArgsNbr, aRArgsNbr : integer): integer;
  end

```

This code is used in section 809.

826. We prefix format objects specified by its kind, its symbol number, and the number of arguments it expects.

When the format object is not found, then 0 will be returned. This is a standard convention in these functions to indicate the thing is missing.

```

⟨ Implementation for MFormatsList 826 ⟩ ≡
const PrefixFormatChars = [‘M’, ‘V’, ‘U’, ‘J’, ‘L’, ‘G’];
function MFormatsList.LookUp_PrefixFormat (aKind : char; aSymNr, aArgsNbr : integer): integer;
  var lFormat: MPrefixFormatObj; i: integer;
  begin MizAssert (3300, aKind ∈ PrefixFormatChars);
  lFormat.Init (aKind, aSymNr, aArgsNbr);
  if Find (@lFormat, i) then LookUp_PrefixFormat ← fIndex↑i + 1
  else LookUp_PrefixFormat ← 0;
  end;

```

This code is used in section 810.

827. Looking up an infix functor format (§815). This returns the *index* for the entry.

The contract here is rather confusing. What *should* occur is: if there is a functor symbol with the given left and right number of arguments, then return the index for the entry. Otherwise (when there is no functor symbol) return -1 .

What happens instead is these values are incremented, so if the functor symbol with the given number of left and right arguments is contained in position k , then $k + 1$ will be returned. If there is no such functor symbol, then 0 will be returned.

```
function MFormatsList.LookUp_FuncFormat(aSymNr, aLArgsNbr, aRArgsNbr : integer): integer;
  var lFormat: MInfixFormatObj; i: integer;
  begin lFormat.Init(␣␣, aSymNr, aLArgsNbr, aRArgsNbr);
  if Find(@lFormat, i) then LookUp_FuncFormat  $\leftarrow$  fIndex↑[i] + 1
  else LookUp_FuncFormat  $\leftarrow$  0;
  end;
```

828. Looking up a bracket.

```
function MFormatsList.LookUp_BracketFormat(aLSymNr, aRSymNr, aArgsNbr, aLArgsNbr,
  aRArgsNbr : integer): integer;
  var lFormat: MBracketFormatObj; i: integer;
  begin lFormat.Init(aLSymNr, aRSymNr, aArgsNbr, aLArgsNbr, aRArgsNbr);
  if Find(@lFormat, i) then LookUp_BracketFormat  $\leftarrow$  fIndex↑[i] + 1
  else LookUp_BracketFormat  $\leftarrow$  0;
  end;
```

829. Looking up a predicate.

```
function MFormatsList.LookUp_PredFormat(aSymNr, aLArgsNbr, aRArgsNbr : integer): integer;
  var lFormat: MInfixFormatObj; i: integer;
  begin lFormat.Init(␣␣, aSymNr, aLArgsNbr, aRArgsNbr);
  if Find(@lFormat, i) then LookUp_PredFormat  $\leftarrow$  fIndex↑[i] + 1
  else LookUp_PredFormat  $\leftarrow$  0;
  end;
```

830. Insert a format, if it's missing.

```
function MFormatsList.CollectFormat(aFormat : MFormatPtr): integer;
  var lFormatNr, i: integer;
  begin lFormatNr  $\leftarrow$  0;
  if ¬Find(aFormat, i) then
    begin lFormatNr  $\leftarrow$  Count + 1; Insert(aFormat);
    end;
  CollectFormat  $\leftarrow$  lFormatNr;
  end;
```

831. Inserting a bracket, if it is missing. Returns the format number for the format, whether it is missing or not.

```
function MFormatsList.CollectBracketForm(aLSymNr, aRSymNr, aArgsNbr, aLArgsNbr,
    aRArgsNbr : integer): integer;
var lFormatNr: integer;
begin lFormatNr  $\leftarrow$  LookUp_BracketFormat(aLSymNr, aRSymNr, aArgsNbr, aLArgsNbr, aRArgsNbr);
if lFormatNr = 0 then
    begin lFormatNr  $\leftarrow$  Count + 1;
        Insert(new(MBracketFormatPtr, Init(aLSymNr, aRSymNr, aArgsNbr, aLArgsNbr, aRArgsNbr)));
    end;
    CollectBracketForm  $\leftarrow$  lFormatNr;
end;
```

832. Inserting a functor format, if it is missing. This returns the format number for the functor (whether it is missing or not).

```
function MFormatsList.CollectFuncForm(aSymNr, aLArgsNbr, aRArgsNbr : integer): integer;
var lFormatNr: integer;
begin lFormatNr  $\leftarrow$  LookUp_FuncFormat(aSymNr, aLArgsNbr, aRArgsNbr);
if lFormatNr = 0 then
    begin lFormatNr  $\leftarrow$  Count + 1;
        Insert(new(MInfixFormatPtr, Init(^0^, aSymNr, aLArgsNbr, aRArgsNbr)));
    end;
    CollectFuncForm  $\leftarrow$  lFormatNr;
end;
```

833. Insert a prefix format if it is missing. Then return the format number for the prefix format, missing or not.

```
function MFormatsList.CollectPrefixForm(aKind : char; aSymNr, aArgsNbr : integer): integer;
var lFormatNr: integer;
begin lFormatNr  $\leftarrow$  LookUp_PrefixFormat(aKind, aSymNr, aArgsNbr);
if lFormatNr = 0 then
    begin lFormatNr  $\leftarrow$  Count + 1; Insert(new(MPrefixFormatPtr, Init(aKind, aSymNr, aArgsNbr)));
    end;
    CollectPrefixForm  $\leftarrow$  lFormatNr;
end;
```

834. Insert a predicate format, if it is missing. Then return the format number, whether the predicate format is missing or not.

```
function MFormatsList.CollectPredForm(aSymNr, aLArgsNbr, aRArgsNbr : integer): integer;
var lFormatNr: integer;
begin lFormatNr  $\leftarrow$  LookUp_PredFormat(aSymNr, aLArgsNbr, aRArgsNbr);
if lFormatNr = 0 then
    begin lFormatNr  $\leftarrow$  Count + 1;
        Insert(new(MInfixFormatPtr, Init(^R^, aSymNr, aLArgsNbr, aRArgsNbr)));
    end;
    CollectPredForm  $\leftarrow$  lFormatNr;
end;
```

835. Constructor. Construct the empty list of formats.

```
constructor MFormatsList.Init(ALimit : Integer);
  begin InitSorted(ALimit, CompareFormats);
end;
```

836. Constructor. Parse an XML file for formats, and populate a format list object with the file's contents.

```
constructor MFormatsList.LoadFormats(fName : string);
  var lEnvFile: XMLInStreamPtr; lValue: integer; lLex: LexemRec;
  begin InitSorted(100, CompareFormats); lEnvFile  $\leftarrow$  new(XMLInStreamPtr, OpenFile(fName));
  with lEnvFile  $\uparrow$  do
    begin NextElementState; XMLASSERT(nElName = XMLElemName[elFormats]);
    NextElementState;
    while  $\neg$ (nState = eEnd)  $\wedge$  (nElName = XMLElemName[elFormat]) do Insert(In_Format(lEnvFile));
    gPriority.Init(10);
    while  $\neg$ (nState = eEnd) do
      begin XMLASSERT(nElName = XMLElemName[elPriority]);
      lLex.Kind  $\leftarrow$  GetAttr(XMLAttrName[atKind])[1];
      lLex.Nr  $\leftarrow$  GetIntAttr(XMLAttrName[atSymbolNr]); MizAssert(3300, lLex.Kind  $\in$  [ $\text{'0'}$ ,  $\text{'L'}$ ,  $\text{'K'}$ ]);
      lValue  $\leftarrow$  GetIntAttr(XMLAttrName[atValue]); gPriority.Assign(ord(lLex.Kind), lLex.Nr, lValue);
      AcceptEndState; NextElementState;
      end;
    end;
  dispose(lEnvFile, Done);
end;
```

837. We can read exactly one format from an XML input stream.

\langle Read formats from an XML input stream 837 $\rangle \equiv$

```
function In_Format(fInFile : XMLInStreamPtr): MFormatPtr;
  var lLex: LexemRec; lArgsNbr, lLeftArgsNbr, lRightSymNr: integer;
  begin with fInFile  $\uparrow$  do
    begin lLex.Kind  $\leftarrow$  GetAttr(XMLAttrName[atKind])[1];
    lLex.Nr  $\leftarrow$  GetIntAttr(XMLAttrName[atSymbolNr]);
    lArgsNbr  $\leftarrow$  GetIntAttr(XMLAttrName[atArgNr]);
    case lLex.Kind of
       $\text{'0'}$ ,  $\text{'R'}$ : begin lLeftArgsNbr  $\leftarrow$  GetIntAttr(XMLAttrName[atLeftArgNr]);
        In_Format  $\leftarrow$  new(MInfixFormatPtr, Init(lLex.Kind, lLex.Nr, lLeftArgsNbr,
          lArgsNbr - lLeftArgsNbr));
        end;
       $\text{'J'}$ ,  $\text{'U'}$ ,  $\text{'V'}$ ,  $\text{'G'}$ ,  $\text{'L'}$ ,  $\text{'M'}$ : In_Format  $\leftarrow$  new(MPrefixFormatPtr, Init(lLex.Kind, lLex.Nr, lArgsNbr));
       $\text{'K'}$ : begin lRightSymNr  $\leftarrow$  GetIntAttr(XMLAttrName[atRightSymbolNr]);
        In_Format  $\leftarrow$  new(MBracketFormatPtr, Init(lLex.Nr, lRightSymNr, lArgsNbr, 0, 0));
        end;
    othercases RunTimeError(2019);
    endcases;
    AcceptEndState; NextElementState;
  end;
end;
```

This code is used in section 810.

838. Conversely, we can print to an output stream an XML representation for a format object.

⟨Implement *MFormatObj* 838⟩ ≡

```
procedure MFormatObj.Out_Format(var fOutFile : XMLOutStreamObj; aFormNr : integer);
begin with fOutFile do
  begin Out_XElStart(XMLElemName[elFormat]); Out_XAttr(XMLAttrName[atKind], fSymbol.Kind);
  if aFormNr > 0 then Out_XIntAttr(XMLAttrName[atNr], aFormNr);
  Out_XIntAttr(XMLAttrName[atSymbolNr], fSymbol.Nr);
  case fSymbol.Kind of
    'J', 'U', 'V', 'G', 'L', 'M':
      Out_XIntAttr(XMLAttrName[atArgNr], MPrefixFormatPtr(@Self)↑.fRightArgsNbr);
    'O', 'R': with MInfixFormatPtr(@Self)↑ do
      begin Out_XIntAttr(XMLAttrName[atArgNr], fLeftArgsNbr + fRightArgsNbr);
      Out_XIntAttr(XMLAttrName[atLeftArgNr], fLeftArgsNbr);
      end;
    'K': with MBracketFormatPtr(@Self)↑ do
      begin Out_XIntAttr(XMLAttrName[atArgNr], fArgsNbr);
      Out_XIntAttr(XMLAttrName[atRightSymbolNr], fRightSymbolNr);
      end;
  othercases RuntimeError(3300);
endcases;
  Out_XElEnd0;
end;
end;
```

This code is used in section 810.

839. Given a list of formats, we can store them to an XML file using the previous function.

```
procedure MFormatsList.StoreFormats(fName : string);
var lEnvFile : XMLOutStreamObj; z : integer;
begin lEnvFile.OpenFile(fName);
with lEnvFile do
  begin Out_XElStart0(XMLElemName[elFormats]);
  for z ← 0 to Count − 1 do MFormatPtr(Items↑[z])↑.Out_Format(lEnvFile, z + 1);
  with gPriority do
    for z ← 0 to fCount − 1 do
      begin Out_XElStart(XMLElemName[elPriority]);
      Out_XAttr(XMLAttrName[atKind], chr(fList↑[z].X1));
      Out_XIntAttr(XMLAttrName[atSymbolNr], fList↑[z].X2);
      Out_XIntAttr(XMLAttrName[atValue], fList↑[z].Y); Out_XElEnd0;
      end;
    Out_XElEnd(XMLElemName[elFormats]);
  end;
lEnvFile.Done;
end;
```

840. We clean up the formats collection and the priority. The *gPriority* is initialized and populated in other functions. The *gFormatsColl* is used heavily in *parseraddition.pas* and a few other places.

```
procedure DisposeFormats;
begin gFormatsColl.Done; gPriority.Done;
end;
```

File 18

Syntax

841. This describes the syntax for the Mizar language, using expressions, subexpressions, blocks, and “items” (statements).

We will need to recall *StackedObj* from `mobjects.pas` (§449).

```

<syntax.pas 841> ≡
  <GNU License 4>
unit syntax;
interface
  uses mobjects, errhan; <Interface for syntax.pas 848>
implementation
  uses mconsole
    mdebug , info end_mdebug;
    <Implementation for syntax.pas 843>
end .

```

842. The maximum number of “visible” arguments to an expression is set here, at 10.

```

<Public constants for syntax.pas 842> ≡
const MaxVisArgNbr = 10;

```

This code is used in section 848.

843. The implementation for the abstract syntax of Mizar is rather uninteresting, since most of the methods are abstract.

```

<Implementation for syntax.pas 843> ≡
  <Subexpression constructor 874>
  <Subexpression destructor 875>
  <Expression constructor 871>
  <Subexpression procedures 878>
  <Create a subexpression for an expression 872>
  <Item object implementation 864>
  <Block object implementation 854>
  <Public procedures implementation for syntax.pas 844>

```

This code is used in section 841.

844. Destructor wrappers. We have a few public-facing procedures to free the global subexpression, expression, etc., variables describing the state of the parser.

```

<Public procedures implementation for syntax.pas 844> ≡
procedure KillSubexpression;
begin if gSubexpPtr = nil then RunTimeError(2144)
else dispose(gSubexpPtr, Done);
end;

```

See also sections 845, 846, and 847.

This code is used in section 843.

845.

```

⟨Public procedures implementation for syntax.pas 844⟩ +≡
procedure KillExpression;
  begin if gExpPtr = nil then RunTimeError(2143)
  else dispose(gExpPtr, Done);
  end;

```

846. This method will not be used until we get to the parser, sadly. I am not sure why there are calls to *DisplayLine* in *KillItem* and *KillBlock*, though.

The *KillItem* is called in exactly two places: (1) *Semicolon* in *parser.pas*, (2) *SchemeBlock*, also in the parser. (And *KillBlock* is called only in the parser, as well.)

```

⟨Public procedures implementation for syntax.pas 844⟩ +≡
procedure KillItem;
  begin if gItemPtr = nil then RunTimeError(2142)
  else begin gItemPtr↑.Pop; dispose(gItemPtr, Done); end;
  DisplayLine(CurPos.Line, ErrorNbr);
  end;

```

847.

```

⟨Public procedures implementation for syntax.pas 844⟩ +≡
procedure KillBlock;
  begin if gBlockPtr = nil then RunTimeError(2141)
  else begin gBlockPtr↑.Pop; dispose(gBlockPtr, Done);
  end;
  DisplayLine(CurPos.Line, ErrorNbr);
  end;

```

848.

```

⟨Interface for syntax.pas 848⟩ ≡
  ⟨Public constants for syntax.pas 842⟩
type ⟨BlockKinds (syntax.pas) 852⟩
  ⟨ItemKinds (syntax.pas) 862⟩
  ⟨ExpKinds (syntax.pas) 869⟩
  ⟨Block object interface 853⟩;
  ⟨Class declaration for Item object 863⟩;
  ⟨Subexpression object class 873⟩;
  ⟨Expression class declaration 870⟩;
  ⟨Public procedures for syntax.pas 849⟩
  ⟨Public variables for syntax.pas 850⟩

```

This code is used in section 841.

```

849.  ⟨Public procedures for syntax.pas 849⟩ ≡
procedure KillBlock;
procedure KillItem;
procedure KillExpression;
procedure KillSubexpression;

```

This code is used in section 848.

850. These global public variables for syntax will be manipulated by the parser.

⟨ Public variables for `syntax.pas` 850 ⟩ ≡

```
var gBlockPtr: BlockPtr = nil; gItemPtr: ItemPtr = nil; gExpPtr: ExpressionPtr = nil;  
    gSubexpPtr: SubexpPtr = nil;
```

This code is used in section 848.

Section 18.1. BLOCK OBJECT

851. The Mizar language is block-structured, so we have a Block represent a sequence of statements contained within a block.

This is extended in `parseraddition.pas`.

Fig. 7. UML class diagram for Block object class.

852. There are about a dozen different kinds of blocks.

$\langle \text{BlockKinds (syntax.pas 852)} \rangle \equiv$
 $\text{BlockKind} = (\text{blMain}, \text{blDiffuse}, \text{blHereby}, \text{blProof}, \text{blDefinition}, \text{blNotation}, \text{blRegistration}, \text{blCase},$
 $\text{blSuppose}, \text{blPublicScheme});$

This code is used in section 848.

853. $\langle \text{Block object interface 853} \rangle \equiv$
 $\text{BlockPtr} = \uparrow \text{BlockObj};$
 $\text{ItemPtr} = \uparrow \text{ItemObj};$
 $\text{BlockObj} = \text{object} (\text{StackedObj})$
 $\text{nBlockKind} : \text{BlockKind};$
constructor $\text{Init}(\text{fBlockKind} : \text{BlockKind});$
procedure $\text{Pop};$ *virtual*; { inheritance }
destructor $\text{Done};$ *virtual*;
procedure $\text{StartProperText};$ *virtual*;
procedure $\text{ProcessLink};$ *virtual*;
procedure $\text{ProcessRedefine};$ *virtual*;
procedure $\text{ProcessBegin};$ *virtual*;
procedure $\text{ProcessPragma};$ *virtual*;
procedure $\text{StartAtSignProof};$ *virtual*;
procedure $\text{FinishAtSignProof};$ *virtual*;
procedure $\text{FinishDefinition};$ *virtual*;
procedure $\text{CreateItem}(\text{fItemKind} : \text{ItemKind});$ *virtual*;
procedure $\text{CreateBlock}(\text{fBlockKind} : \text{BlockKind});$ *virtual*;
procedure $\text{StartSchemeDemonstration};$ *virtual*;
procedure $\text{FinishSchemeDemonstration};$ *virtual*;
end

This code is used in section 848.

854. The constructor for a Block will initialize its *Previous* pointer to point at the global *gBlockPtr* instance.

$\langle \text{Block object implementation 854} \rangle \equiv$
constructor $\text{BlockObj.Init}(\text{fBlockKind} : \text{BlockKind});$
 begin $\text{nBlockKind} \leftarrow \text{fBlockKind}; \text{Previous} \leftarrow \text{gBlockPtr};$
 end;

See also sections 855, 856, 857, 858, 859, and 860.

This code is used in section 843.

855. Note that popping a block object is left for subclasses to handle.

```
⟨Block object implementation 854⟩ +≡
procedure BlockObj.Pop;
  begin end;
```

```
856. ⟨Block object implementation 854⟩ +≡
destructor BlockObj.Done;
  begin gBlockPtr ← BlockPtr(Previous);
  end;
```

857. Abstract methods.

```
⟨Block object implementation 854⟩ +≡
procedure BlockObj.StartProperText;
  begin end;
procedure BlockObj.ProcessRedefine;
  begin end;
procedure BlockObj.ProcessLink;
  begin end;
procedure BlockObj.ProcessBegin;
  begin end;
procedure BlockObj.ProcessPragma;
  begin end;
procedure BlockObj.StartAtSignProof;
  begin end;
procedure BlockObj.FinishAtSignProof;
  begin end;
procedure BlockObj.FinishDefinition;
  begin end;
```

```
858. ⟨Block object implementation 854⟩ +≡
procedure BlockObj.CreateItem(fItemKind : ItemKind);
  begin gItemPtr ← new(ItemPtr, Init(fItemKind));
  end;
```

```
859. ⟨Block object implementation 854⟩ +≡
procedure BlockObj.CreateBlock(fBlockKind : BlockKind);
  begin gBlockPtr ← new(BlockPtr, Init(fBlockKind));
  end;
```

860. More abstract methods.

```
⟨Block object implementation 854⟩ +≡
procedure BlockObj.StartSchemeDemonstration;
  begin end;
procedure BlockObj.FinishSchemeDemonstration;
  begin end;
```

Section 18.2. ITEM OBJECTS

861. The class declaration for an *Item* object is depressingly long, with most of its virtual methods not used. The class diagram is worth drawing out.

Fig. 8. UML class diagram for Item object class.

862. Items are a tagged union, tagged by the “kind” of item.

⟨ItemKinds (syntax.pas) 862⟩ ≡

```

ItemKind = (itIncorrItem, itDefinition, itSchemeBlock, itSchemeHead, itTheorem, itAxiom,
itReservation, itCanceled, itSection, itRegularStatement, itChoice, itReconsider, itPrivFuncDefinition,
itPrivPredDefinition, itConstantDefinition, itGeneralization, itLocDeclaration,
itExistentialAssumption, itExemplification, itPerCases, itConclusion, itCaseBlock, itCaseHead,
itSupposeHead, itAssumption, itCorrCond, itCorrectness, itProperty, itDefPred, itDefFunc,
itDefMode, itDefAttr, itDefStruct, itPredSynonym, itPredAntonym, itFuncNotation, itModeNotation,
itAttrSynonym, itAttrAntonym, itCluster, itIdentify, itReduction, itPropertyRegistration, itPragma);

```

This code is used in section 848.

863. ⟨Class declaration for Item object 863⟩ ≡

```

ItemObj = object (StackedObj)
  nItemKind: ItemKind;
  constructor Init(fItemKind : ItemKind);
  procedure Pop; virtual;
  destructor Done; virtual;
  ⟨Method declarations for Item object 867⟩
end

```

This code is used in section 848.

864. It is particularly important to note, when constructing an *Item* object, the previous item will *automatically* be set to point to the global *gItem* variable.

⟨Item object implementation 864⟩ ≡

```

constructor ItemObj.Init(fItemKind : ItemKind);
  begin nItemKind ← fItemKind; Previous ← gItemPtr;
  end;
procedure ItemObj.Pop;
  begin DisplayLine(CurPos.Line, ErrorNbr);
  end;
destructor ItemObj.Done;
  begin DisplayLine(CurPos.Line, ErrorNbr); gItemPtr ← ItemPtr(Previous);
  end;

```

See also sections 865 and 868.

This code is used in section 843.

865. Creating an expression in an item is handled with this method.

⟨Item object implementation 864⟩ +≡

```
procedure ItemObj.CreateExpression(fExpKind : ExpKind);
  begin gExpPtr ← new(ExpressionPtr, Init(fExpKind));
  end;
```

866. Abstract methods. The methods of the *Item* class can be partitioned into two groups: those which will be implemented by a subclass, and those which will remain “empty” (i.e., whose body is just **begin end**).

⟨Methods overridden by extended Item class 866⟩ ≡

Section 18.3. EXPRESSIONS**869.**

⟨ExpKinds (syntax.pas) 869⟩ ≡
ExpKind = (*exNull*, *exType*, *exTerm*, *exFormula*, *exResType*, *exAdjectiveCluster*);

This code is used in section 848.

870. ⟨Expression class declaration 870⟩ ≡

ExpressionPtr = ↑*ExpressionObj*;
ExpressionObj = **object** (*MObject*)
 nExpKind: *ExpKind*;
 constructor *Init*(*fExpKind* : *ExpKind*);
 procedure *CreateSubexpression*; *virtual*;
end

This code is used in section 848.

871. Constructor.

⟨Expression constructor 871⟩ ≡
constructor *ExpressionObj.Init*(*fExpKind* : *ExpKind*);
 begin *nExpKind* ← *fExpKind*;
 end;

This code is used in section 843.

872. Observe that creating a subexpression (1) allocates a new *SubexpPtr* on the heap, and (2) mutates the *gSubexpPtr* global variable.

⟨Create a subexpression for an expression 872⟩ ≡
procedure *ExpressionObj.CreateSubexpression*;
 begin *gSubexpPtr* ← *new*(*SubexpPtr*, *Init*);
 end;

This code is used in section 843.

Section 18.4. SUBEXPRESSIONS**873.**

```

⟨ Subexpression object class 873 ⟩ ≡
  SubexpPtr = ↑SubexpObj;
  SubexpObj = object (StackedObj)
    constructor Init;
    destructor Done; virtual;
    ⟨ Empty method declarations for SubexpObj 877 ⟩
end

```

This code is used in section 848.

874. Constructor. Importantly, constructing a new *Subexp* object will initialize its *Previous* field to point to the global *gSubexpPtr* object.

```

⟨ Subexpression constructor 874 ⟩ ≡
constructor SubexpObj.Init;
  begin Previous ← gSubexpPtr;
end;

```

This code is used in section 843.

875. Destructor.

```

⟨ Subexpression destructor 875 ⟩ ≡
destructor SubexpObj.Done;
  begin gSubexpPtr ← SubexpPtr(Previous);
end;

```

This code is used in section 843.

876. The remaining methods for subexpression objects are empty.

⟨Methods implemented by subclasses of *SubexpObj* 876⟩ ≡

```

File 19

MScanner

879. We have the MScanner module transform an article (an input file) into a stream of tokens.

```

< scanner.pas 748 > +≡
  < GNU License 4 >
unit mscanner;
interface
  uses errhan, mobjects, scanner;
  < Public interface for MScanner 880 >
implementation
  uses mizenv;
  < Implementation for MScanner 886 >;

end .

```

880. Public types. We have enumerated types for each construction we'll encounter in Mizar.

```

< Public interface for MScanner 880 > ≡
type < Token kinds for MScanner 884 >;
  CorrectnessKind = (syCorrectness, syCoherence, syCompatibility, syConsistency, syExistence,
    syUniqueness, syReducibility);
  PropertyKind = (sErrProperty, sySymmetry, syReflexivity, syIrreflexivity, syAssociativity, syTransitivity,
    syCommutativity, syConnectedness, syAsymmetry, syIdempotence, syInvolutiveness, syProjectivity,
    sySethood, syAbstractness);
  LibraryReferenceKind = (syThe, syDef, sySch);
  DirectiveKind = (syVocabularies, syNotations, syDefinitions, syTheorems, sySchemes, syRegistrations,
    syConstructors, syRequirements, syEqualities, syExpansions);
  < Token type for MScanner 881 >;

```

See also sections 882 and 883.

This code is used in section 879.

881. Token type for MScanner.

```

< Token type for MScanner 881 > ≡
  Token = record Kind: TokenKind;
    Nr: integer;
    Spelling: string;
  end

```

This code is used in section 880.

882. Constants for MScanner

```

⟨Public interface for MScanner 880⟩ +≡
const { Homonymic and special symbols in buildin vocabulary }
    { Homonymic Selector Symbol }
    StrictSym = 1; { “strict” }
    { Homonymic Mode Symbol }
    SetSym = 1; { ‘set’ }
    { Homonymic Predicate Symbol }
    EqualitySym = 1; { ‘=’ }
    { Homonymic Circumfix Symbols }
    SquareBracket = 1; { ‘[’ ‘]’ }
    CurlyBracket = 2; { “_” “”” }
    RoundedBracket = 3; { “(” “)” }
    scTooLongLineErrorNr = 200; { Error number: Too long line }
⟨Token names for MScanner 885⟩;
CorrectnessName: array [CorrectnessKind] of string = (‘correctness’, ‘coherence’,
    ‘compatibility’, ‘consistency’, ‘existence’, ‘uniqueness’, ‘reducibility’);
PropertyName: array [PropertyKind] of string = (‘’, ‘symmetry’, ‘reflexivity’, ‘irreflexivity’,
    ‘associativity’, ‘transitivity’, ‘commutativity’, ‘connectedness’, ‘asymmetry’,
    ‘idempotence’, ‘involutiveness’, ‘projectivity’, ‘sethood’, ‘abstractness’);
LibraryReferenceName: array [LibraryReferenceKind] of string = (‘the’, ‘def’, ‘sch’);
DirectiveName: array [DirectiveKind] of
    string = (‘vocabularies’, ‘notations’, ‘definitions’, ‘theorems’, ‘schemes’, ‘registrations’,
    ‘constructors’, ‘requirements’, ‘equalities’, ‘expansions’);
PlaceholderName: array [1 .. 10] of
    string = (‘$1’, ‘$2’, ‘$3’, ‘$4’, ‘$5’, ‘$6’, ‘$7’, ‘$8’, ‘$9’, ‘$10’);
Unexpected = sErrProperty;

```

883. Public facing procedures and global variables. Of particular importance, the global variable *gScanner* is declared here.

```

⟨Public interface for MScanner 880⟩ +≡
var PrevWord, CurWord, AheadWord: Token;
    PrevPos, AheadPos: Position;
procedure ReadToken;
procedure LoadPrf(const aPrfFileName: string);
procedure DisposePrf;
procedure StartScanner;
procedure InitSourceFile(const aFileName, aDctFileName: string);
procedure CloseSourceFile;
procedure InitScanning(const aFileName, aDctFileName: string);
procedure FinishScanning;
var gScanner: MScannPtr = nil; { This is important }
    ModeMaxArgs, StructModeMaxArgs, PredMaxArgs: IntSequence;

```

884. Token kinds. If I were cleverer, I would have some **WEB** macros to make this readable.

⟨Token kinds for MScanner 884⟩ ≡

This code is used in section [882](#).

886. Reading a token. This tokenizes a Mizar article, using the scanner's *GetToken* method. We can trace this *GetToken* back to its implementation (§789). This, in turn, depends on the *SliceIt* method (§772).

This method is used to determine the next token in `parser.pas`'s *Parse* function.

This assumes that *StartScanner* (§889) has been invoked already, which initializes the *CurWord* token and other variables.

Also important to observe: the *Kind* of the token is populated here.

⟨Implementation for MScanner 886⟩ ≡

```
procedure ReadToken;
begin PrevWord ← CurWord; PrevPos ← CurPos; CurWord ← AheadWord; CurPos ← AheadPos;
    { ' ' is not allowed in an identifiers in the text proper }
if (CurWord.Kind = sy_Begin) then gScanner↑.Allowed[' ' ] ← 0;
if (CurWord.Kind = sy_Error) ∧ (CurWord.Nr = scTooLongLineErrorNr) then
    ErrImm(CurWord.Nr);
gScanner↑.GetToken;
AheadWord.Kind ← TokenKind(gScanner↑.fLexem.Kind); AheadWord.Nr ← gScanner↑.fLexem.Nr;
AheadWord.Spelling ← gScanner↑.fStr; AheadPos ← gScanner↑.fPos;
end;
```

See also sections 887, 888, 889, 890, 891, 892, and 893.

This code is used in section 879.

887. Loading a proof file. The `.prf` file is a file containing numerals, and its usage eludes me. The format consists of multiple lines:

Line 1: Three non-negative integers are on the first line “*M S P*”

Line 2: Contains *M* non-negative integers separated by a single whitespace

Line 3: Contains *S* non-negative integers separated by a single whitespace

Line 4: Contains *P* non-negative integers separated by a single whitespace.

This function loads the contents of the `.prf` file. This initializes the global variables *ModeMaxArgs*, *StructureModeMaxArgs*, *PredMaxArgs*, then populates them.

⟨Implementation for MScanner 886⟩ +≡

```
procedure LoadPrf(const aPrfFileName: string);
var lPrf: text; lModeMaxArgsSize, lStructModeMaxArgsSize, lPredMaxArgsSize, i, lInt, r: integer;
begin assign(lPrf, aPrfFileName + '.prf'); reset(lPrf);
    Read(lPrf, lModeMaxArgsSize, lStructModeMaxArgsSize, lPredMaxArgsSize);
    ModeMaxArgs.Init(lModeMaxArgsSize + 1); r ← ModeMaxArgs.Insert(0);
    StructModeMaxArgs.Init(lStructModeMaxArgsSize + 1); r ← StructModeMaxArgs.Insert(0);
    PredMaxArgs.Init(lPredMaxArgsSize + 1); r ← PredMaxArgs.Insert(0);
for i ← 1 to lModeMaxArgsSize do
    begin Read(lPrf, lInt); r ← ModeMaxArgs.Insert(lInt);
    end;
for i ← 1 to lStructModeMaxArgsSize do
    begin Read(lPrf, lInt); r ← StructModeMaxArgs.Insert(lInt);
    end;
for i ← 1 to lPredMaxArgsSize do
    begin Read(lPrf, lInt); r ← PredMaxArgs.Insert(lInt);
    end;
    close(lPrf);
end;
```

888. We cleanup after using the `.prf` file.

⟨Implementation for MScanner 886⟩ +≡

```
procedure DisposePrf;
  begin ModeMaxArgs.Done; PredMaxArgs.Done; StructModeMaxArgs.Done;
  end;
```

889. We construct an MScann object to scan a file.

⟨Implementation for MScanner 886⟩ +≡

```
procedure StartScanner;
  begin CurPos.Line ← 1; CurPos.Col ← 0; AheadWord.Kind ← TokenKind(gScanner↑.fLexem.Kind);
  AheadWord.Nr ← gScanner↑.fLexem.Nr; AheadWord.Spelling ← gScanner↑.fStr;
  AheadPos ← gScanner↑.fPos;
  end;
```

890. We initialize a scanner for a file.

⟨Implementation for MScanner 886⟩ +≡

```
procedure InitSourceFile(const aFileName, aDctFileName: string);
  begin new(gScanner, InitScanning(aFileName, aDctFileName)); StartScanner;
  end;
```

891. When we're done with a scanner, we call the destructor for the MScanner.

⟨Implementation for MScanner 886⟩ +≡

```
procedure CloseSourceFile;
  begin dispose(gScanner, Done);
  end;
```

892. We can combine the previous functions together to initialize a scanner for a file (an article) and its dictionary file.

⟨Implementation for MScanner 886⟩ +≡

```
procedure InitScanning(const aFileName, aDctFileName: string);
  begin gScanner ← new(MScannPtr, InitScanning(aFileName, aDctFileName)); StartScanner;
  LoadPrf(aDctFileName);
  end;
```

893. We cleanup after scanning, saving a dictionary XML file to an “`.idx`” file. This uses the global variable *EnvFileName* declared in `mizenv.pas` (§36).

⟨Implementation for MScanner 886⟩ +≡

```
procedure FinishScanning;
  begin gScanner↑.fIdents.SaveXDct(EnvFileName + ‘.idx’); CloseSourceFile; DisposePrf;
  end;
```

File 20

Abstract Syntax

894. A crucial step in any interpreter, compiler, or proof assistant is to transform the concrete syntax into an abstract syntax tree. This module provides all the classes for the abstract syntax tree *of expressions, types, and formulas* in Mizar. The abstract syntax tree for “statements” will be found in the “Weakly Strict Text Proper” module.

This is a bit, well, “Java-esque”, in the sense that each different kind of node in the abstract syntax tree is represented by a different class. If you don’t know abstract syntax trees, I can heartily recommend Bob Nystrom’s *Crafting Interpreters* ([Ch. 5: Representing Code](#)) for an overview.

I’ll be quoting from the grammar for Mizar as we go along, since the class hierarchy names their classes after the nonterminal symbols in the grammar. (It’s what anyone would do.) You can find a local copy of the grammar on most UNIX machines with Mizar installed located at `/usr/local/doc/Mizar/syntax.txt`, which you can study at your leisure.

895. Warning: There is a lot of boiler plate code in the constructors and destructors. I am going to pass over them without much comment, because they are monotonous and uninteresting. The more interesting part will be discussed with the class declarations for each kind of node. I will simply entitle the paragraphs “Constructor” to indicate I am recognizing their existence and moving on.

```

< abstract_syntax.pas 895 > ≡
  < GNU License 4 >
unit abstract_syntax;
  interface uses errhan, mobjects, syntax;
    < Interface for abstract syntax 897 >
  implementation
    < Implementation of abstract syntax 896 >
  end .

```

896. The implementation requires discussing a few “special cases” (variables, qualified segments, adjectives) before getting to the usual syntactic classes (terms, types, formulas).

```

< Implementation of abstract syntax 896 > ≡
  < Variable AST constructor 899 >
  < Qualified segment AST constructor 902 >
  < Adjective expression AST constructor 908 >
  < Adjective AST constructor 912 >
  < Negated adjective AST constructor 910 >
  < Implementing term AST 917 >
  < Implementing type AST 959 >
  < Implementing formula AST 971 >
  < Within expression AST implementation 1011 >

```

This code is used in section [895](#).

897. The interface consists mostly of classes, as well as a few enumerated types. The gambit resembles what we would do if we were programming in C: define an **enum TermSort**, then introduce a **struct TermAstNode** {**enum TermSort sort**; } to act as an abstract base class for terms (and do likewise for formulas, types, etc.). This allows us to use “struct inheritance” in C, as Bob Nystrom’s *Crafting Interpreters* (Ch. 19) calls it.

```

⟨Interface for abstract syntax 897⟩ ≡
type ⟨Abstract base class for types 957⟩;
  ⟨Abstract base class for terms 913⟩;
  ⟨Abstract base class for formulas 968⟩;
  ⟨Adjective expression (abstract syntax tree) 907⟩;
  ⟨Negated adjective expression (abstract syntax tree) 909⟩;
  ⟨Adjective (abstract syntax tree) 911⟩;
  { Auxiliary structures }
  ⟨Variable (abstract syntax tree) 898⟩;
  ⟨Qualified segment (abstract syntax tree) 901⟩;
  ⟨Classes for terms (abstract syntax tree) 915⟩
  ⟨Classes for type (abstract syntax tree) 958⟩
  ⟨Classes for formula (abstract syntax tree) 970⟩
  { _____ }
  ⟨Class for Within expression 1010⟩;

```

This code is used in section 895.

898. Variable. A variable in the abstract syntax tree is basically a de Bruijn index, in the sense that it is represented by an integer in the metalanguage (PASCAL).

Logicians may feel uncomfortable at variables being outside the term syntax tree. But what logicians think of as “variables” in first-order logic, Mizar calls them “Simple Terms” (§916).

```

⟨Variable (abstract syntax tree) 898⟩ ≡
  VariablePtr = ↑VariableObj;
  VariableObj = object (MObject)
    nIdent: integer; { identifier number }
    nVarPos: Position;
    constructor Init(const aPos: Position; aIdentNr: integer);
end

```

This code is used in section 897.

899. Constructor.

```

⟨Variable AST constructor 899⟩ ≡
constructor VariableObj.Init(const aPos: Position; aIdentNr: integer);
  begin nIdent ← aIdentNr; nVarPos ← aPos;
end;

```

This code is used in section 896.

900. Qualified segment. A qualified segment refers to situations in, e.g., “**consider** $\langle \text{qualified-segment} \rangle^+$ **such that** ...”. This also happens in quantifiers where the Working Mathematician writes $\forall \vec{x}. P[\vec{x}]$, for example (that quantifier prefix “ $\forall \vec{x}$ ” uses the qualifying segment \vec{x}).

The Mizar grammar for qualified segments looks like:

```

Qualified-Variables = Implicitly-Qualified-Variables
                    | Explicitly-Qualified-Variables
                    | Explicitly-Qualified-Variables "," Implicitly-Qualified-Variables .
Implicitly-Qualified-Variables = Variables .
Explicitly-Qualified-Variables = Qualified-Segment {" ," Qualified-Segment }.
Qualified-Segment = Variables Qualification .
Variables = Variable-Identifier {" ," Variable-Identifier }.
Qualification = ( "being" | "be" ) Type-Expression .

```

We will implement `Qualified-Variables` as an array of pointers to *QualifiedSegment* objects, each one being either implicit or explicit.

901. Abstract base class for qualified segments. We have *implicitly* qualified segments and *explicitly* qualified segments, which are “both” qualified segments. Object-oriented yoga teaches us to describe this situation using a “qualified segment” abstract base class, and then extend it with two subclasses.

```

⟨ Qualified segment (abstract syntax tree) 901 ⟩ ≡
  SegmentKind = ( ikImplQualifiedSegm, ikExplQualifiedSegm );
  QualifiedSegmentPtr = ↑ QualifiedSegmentObj;
  QualifiedSegmentObj = object ( MObject )
    nSegmPos: Position;
    nSegmentSort: SegmentKind;
    constructor Init(const aPos: Position; aSort: SegmentKind);
  end

```

See also sections 903 and 905.

This code is used in section 897.

902. Constructor.

```

⟨ Qualified segment AST constructor 902 ⟩ ≡
  constructor QualifiedSegmentObj.Init(const aPos: Position; aSort: SegmentKind);
  begin nSegmPos ← aPos; nSegmentSort ← aSort;
  end;

```

See also sections 904 and 906.

This code is used in section 896.

903. Implicitly qualified segments. When we use “reserved variables” in the qualifying segment, we can suppress the type ascription (i.e., the “**being** $\langle \text{Type} \rangle$ ”). This makes the typing *implicit*. Hence the name *implicitly* qualified segments (the types are implicitly given).

```

⟨ Qualified segment (abstract syntax tree) 901 ⟩ +≡
  ImplicitlyQualifiedSegmentPtr = ↑ ImplicitlyQualifiedSegmentObj;
  ImplicitlyQualifiedSegmentObj = object ( QualifiedSegmentObj )
    nIdentifier: VariablePtr;
    constructor Init(const aPos: Position; aIdentifier: VariablePtr);
    destructor Done; virtual;
  end ;

```

904. Constructor. The constructors and destructors for implicitly qualified segments are straightforward.

```

< Qualified segment AST constructor 902 > +≡
constructor ImplicitlyQualifiedSegmentObj.Init(const aPos: Position; aIdentifier: VariablePtr);
  begin inherited Init(aPos, ikImplQualifiedSegm); nIdentifier ← aIdentifier;
  end;
destructor ImplicitlyQualifiedSegmentObj.Done;
  begin dispose(nIdentifier, Done);
  end;

```

905. Explicitly qualified segment. The other possibility in Mizar is that we will have “explicitly typed variables” in the qualifying segment. The idea is that, in Mizar, we can permit the following situation:

consider *x, y, z* being set such that ...

This means the three variables *x*, *y*, *z* are explicitly qualified variables with the type “set”. We represent this using one *ExplicitlyQualifiedSegment* object, a vector for the identifiers (*x*, *y*, *z*) and a pointer to their type (set).

```

< Qualified segment (abstract syntax tree) 901 > +≡
  ExplicitlyQualifiedSegmentPtr = ↑ExplicitlyQualifiedSegmentObj;
  ExplicitlyQualifiedSegmentObj = object (QualifiedSegmentObj)
    nIdentifiers: PList; { of identifier numbers }
    nType: TypePtr;
    constructor Init(const aPos: Position; aIdentifiers: PList; aType: TypePtr);
    destructor Done; virtual;
  end

```

906. The constructors and destructors for explicitly qualified segments are straightforward.

```

< Qualified segment AST constructor 902 > +≡
constructor ExplicitlyQualifiedSegmentObj.Init(const aPos: Position;
  aIdentifiers: PList;
  aType: TypePtr);
  begin inherited Init(aPos, ikExplQualifiedSegm); nIdentifiers ← aIdentifiers; nType ← aType;
  end;
destructor ExplicitlyQualifiedSegmentObj.Done;
  begin dispose(nIdentifiers, Done); dispose(nType, Done);
  end;

```

907. Attributes. Attributes can have arguments *preceding* it. The relevant part of the Mizar grammar, I think, is:

```

  Adjective-Cluster = { Adjective } .
  Adjective = [ "non" ] [ Adjective-Arguments ] Attribute-Symbol .

```

```

< Adjective expression (abstract syntax tree) 907 > ≡
  AdjectiveSort = (wsNegatedAdjective, wsAdjective);
  AdjectiveExpressionPtr = ↑AdjectiveExpressionObj;
  AdjectiveExpressionObj = object (MObject)
    nAdjectivePos: Position;
    nAdjectiveSort: AdjectiveSort;
    constructor Init(const aPos: Position; aSort: AdjectiveSort);
    destructor Done; virtual;
  end

```

This code is used in section 897.

908. \langle Adjective expression AST constructor 908 $\rangle \equiv$
constructor *AdjectiveExpressionObj.Init*(**const** *aPos*: *Position*; *aSort*: *AdjectiveSort*);
 begin *nAdjectivePos* \leftarrow *aPos*; *nAdjectiveSort* \leftarrow *aSort*;
 end;
destructor *AdjectiveExpressionObj.Done*;
 begin end;

This code is used in section 896.

909. Negated adjective. We represent an adjective using the EBNF grammar (c.f., the WSM article-related function *InWSMizFileObj.Read_Adjective:AdjectiveExpressionPtr*):

Negated-Adjective ::= "non" *Adjective-Expr*;
Positive-Adjective ::= [*Adjective-Arguments*] *Attribute-Symbol*;
Adjective-Expr ::= *Negated-Adjective* | *Positive-Adjective*;

Hence we only really need a pointer to the “adjective being negated”.

\langle Negated adjective expression (abstract syntax tree) 909 $\rangle \equiv$
NegatedAdjectivePtr = \uparrow *NegatedAdjectiveObj*;
NegatedAdjectiveObj = **object** (*AdjectiveExpressionObj*)
 nArg: *AdjectiveExpressionPtr*; { of *TermPtr*, visible arguments }
 constructor *Init*(**const** *aPos*: *Position*; *aArg*: *AdjectiveExpressionPtr*);
 destructor *Done*; *virtual*;
 end

This code is used in section 897.

910. Constructor.

\langle Negated adjective AST constructor 910 $\rangle \equiv$
constructor *NegatedAdjectiveObj.Init*(**const** *aPos*: *Position*; *aArg*: *AdjectiveExpressionPtr*);
 begin *inherited Init*(*aPos*, *wsNegatedAdjective*); *nArg* \leftarrow *aArg*;
 end;
destructor *NegatedAdjectiveObj.Done*;
 begin *dispose*(*nArg*, *Done*);
 end;

This code is used in section 896.

911. Adjective objects. [[This is the preferred node for later intermediate representations for attributes, since *nNegated* is a field in the class.]]

\langle Adjective (abstract syntax tree) 911 $\rangle \equiv$
AdjectivePtr = \uparrow *AdjectiveObj*;
AdjectiveObj = **object** (*AdjectiveExpressionObj*)
 nAdjectiveSymbol: *integer*;
 nNegated: *boolean*;
 nArgs: *PList*; { of *TermPtr*, visible arguments }
 constructor *Init*(**const** *aPos*: *Position*; *aAdjectiveNr*: *integer* ; *aArgs*: *PList*);
 destructor *Done*; *virtual*;
 end

This code is used in section 897.

912. Constructor.

$\langle \text{Adjective AST constructor } 912 \rangle \equiv$

```
constructor AdjectiveObj.Init(const aPos: Position; aAdjectiveNr: integer; aArgs: PList);
  begin inherited Init(aPos, wsAdjective); nAdjectiveSymbol  $\leftarrow$  aAdjectiveNr; nArgs  $\leftarrow$  aArgs;
  end;
destructor AdjectiveObj.Done;
  begin dispose(nArgs, Done);
  end;
```

This code is used in section 896.

Section 20.1. TERMS (ABSTRACT SYNTAX TREE)

913. We have an abstract base class for terms, along with the “sorts” (syntactic subclasses) allowed. This allows, e.g., formulas, to refer to terms without knowing the sort of term involved. The UML class diagram for term:

Fig. 9. UML class diagram for abstract syntax tree for terms.

The arrows indicate inheritance, pointing from the subclass to the parent superclass. The abstract base class *TermExpression* is italicized, but it is so difficult to distinguish we have colored it yellow.

NOTE: the class UML diagram may be missing a few descendents of *TermExpression*, but it contains the important subclasses which I could fit into it.

⟨ Abstract base class for terms 913 ⟩ ≡

```

TermSort = (wsErrorTerm, wsPlaceholderTerm, wsNumeralTerm, wsSimpleTerm,
            wsPrivateFunctorTerm, wsInfixTerm, wsCircumfixTerm, wsAggregateTerm, wsForgetfulFunctorTerm,
            wsInternalForgetfulFunctorTerm, wsSelectorTerm, wsInternalSelectorTerm, wsQualificationTerm,
            wsGlobalChoiceTerm, wsSimpleFraenkelTerm, wsFraenkelTerm, wsItTerm, wsExactlyTerm);
TermPtr = ↑TermExpressionObj;
TermExpressionObj = object (MObject)
  nTermSort: TermSort;
  nTermPos: Position;
end

```

This code is used in section 897.

914. The grammar for term expressions in Mizar as stated in `syntax.txt`:

```
Term-Expression = "(" Term-Expression ")"
| [ Arguments ] Functor-Symbol [ Arguments ]
| Left-Functor-Bracket Term-Expression-List Right-Functor-Bracket
| Functor-Identifier "(" [ Term-Expression-List ] ")"
| Structure-Symbol "(#" Term-Expression-List "#)"
| "the" Structure-Symbol "of" Term-Expression
| Variable-Identifier
| "{" Term-Expression { Postqualification } ":" Sentence "}"
| "the" "set" "of" "all" Term-Expression { Postqualification }
| Numeral
| Term-Expression "qua" Type-Expression
| "the" Selector-Symbol "of" Term-Expression
| "the" Selector-Symbol
| "the" Type-Expression
| Private-Definition-Parameter
| "it" .
```

But I think it might be clearer if we view it using the equivalent grammar:

```
Term-Expression = "(" Term-Expression ")"
| [ Arguments ] Functor-Symbol [ Arguments ]
| Left-Functor-Bracket Term-Expression-List Right-Functor-Bracket
| Functor-Identifier "(" [ Term-Expression-List ] ")"
| Aggregate-Term
| Forgetful-Functor-Term
| Variable-Identifier
| Fraenkel-Term
| Numeral
| Qualified-Term
| Selector-Functor
| Internal-Selector-Functor
| Choice-Term
| Private-Definition-Parameter
| "it" .

Aggregate-Term = Structure-Symbol "(#" Term-Expression-List "#)" .
Choice-Term = "the" Type-Expression.
Forgetful-Functor-Term = "the" Structure-Symbol "of" Term-Expression.
Fraenkel-Term = "{" Term-Expression {Postqualification} ":" Sentence "}"
| "the" "set" "of" "all" Term-Expression { Postqualification }.
Internal-Selector-Functor = "the" Selector-Symbol.
Selector-Functor = "the" Selector-Symbol "of" Term-Expression.
Qualified-Term = Term-Expression "qua" Type-Expression.
```

915. Class structure for this syntax tree.

```

⟨Classes for terms (abstract syntax tree) 915⟩ ≡
  { Terms }
  ⟨Simple term (abstract syntax tree) 916⟩;
  ⟨Placeholder term (abstract syntax tree) 918⟩;
  ⟨Numeral term (abstract syntax tree) 920⟩;
  ⟨Infix term (abstract syntax tree) 922⟩;
  ⟨Terms with arguments (abstract syntax tree) 924⟩;
  ⟨Circumfix term (abstract syntax tree) 926⟩;
  ⟨Private functor term (abstract syntax tree) 928⟩;
  ⟨One-argument term (abstract syntax tree) 930⟩;
  ⟨Selector term (abstract syntax tree) 932⟩;
  ⟨Internal selector term (abstract syntax tree) 934⟩;
  ⟨Aggregate term (abstract syntax tree) 936⟩;
  ⟨Forgetful functor (abstract syntax tree) 938⟩;
  ⟨Internal forgetful functors (abstract syntax tree) 940⟩;
  ⟨Fraenkel terms (abstract syntax tree) 942⟩;
  ⟨Exactly term (abstract syntax tree) 948⟩;
  ⟨Qualified term (abstract syntax tree) 946⟩;
  ⟨Choice term (abstract syntax tree) 950⟩;
  ⟨“It” term (abstract syntax tree) 952⟩;
  ⟨Incorrect term (abstract syntax tree) 954⟩;

```

This code is used in section 897.

916. Simple terms. Mizar describes variables *as terms* as a *SimpleTerm*.

```

⟨Simple term (abstract syntax tree) 916⟩ ≡
  SimpleTermPtr = ↑SimpleTermObj;
  SimpleTermObj = object (TermExpressionObj)
    nIdent: integer; { identifier number }
    constructor Init(const aPos: Position; aIdentNr: integer);
  end

```

This code is used in section 915.

917. Constructors.

```

⟨Implementing term AST 917⟩ ≡
constructor SimpleTermObj.Init(const aPos: Position; aIdentNr: integer);
  begin nTermPos ← aPos; nTermSort ← wsSimpleTerm; nIdent ← aIdentNr;
  end;

```

See also sections 919, 921, 923, 925, 927, 929, 931, 933, 935, 937, 939, 941, 943, 945, 947, 949, 951, 953, and 955.

This code is used in section 896.

918. Placeholder terms. These are the parameters “\$1”, “\$2”, etc., which appear in a private functor “`deffunc Foo(object) = ...`”.

```

⟨Placeholder term (abstract syntax tree) 918⟩ ≡
  PlaceholderTermPtr = ↑PlaceholderTermObj; { placeholder }
  PlaceholderTermObj = object (TermExpressionObj)
    nLocusNr: integer; { $1, ... }
    constructor Init(const aPos: Position; aLocusNr: integer);
  end

```

This code is used in section 915.

919. Constructor.

⟨Implementing term AST 917⟩ +≡
constructor *PlaceholderTermObj*.Init(**const** *aPos*: *Position*; *aLocusNr*: *integer*);
 begin *nTermPos* ← *aPos*; *nTermSort* ← *wsPlaceholderTerm*; *nLocusNr* ← *aLocusNr*;
 end;

920. Numeral terms. Mizar can handle 32-bit integers. If we wanted to extend this to, say, arbitrary precision arithmetic, then we would want to modify this class (and a few other places).

⟨Numeral term (abstract syntax tree) 920⟩ ≡
 NumeralTermPtr = ↑*NumeralTermObj*;
 NumeralTermObj = **object** (*TermExpressionObj*)
 nValue: *integer*;
 constructor *Init*(**const** *aPos*: *Position*; *aValue*: *integer*);
 end

This code is used in section 915.

921. Constructor.

⟨Implementing term AST 917⟩ +≡
constructor *NumeralTermObj*.Init(**const** *aPos*: *Position*; *aValue*: *integer*);
 begin *nTermPos* ← *aPos*; *nTermSort* ← *wsNumeralTerm*; *nValue* ← *aValue*;
 end;

922. Infix terms. When we have infix binary operators, they are terms with arguments on both sides of it. For example $x + 2$ will have “+” be an infix term with arguments $(x, 2)$.

We *could* permit multiple arguments on the left-hand side (and on the right-hand side), but they are comma-separated in Mizar. This could happen in finite group theory, for example, “**p -signalizer over** H, G ” has two arguments on the right but only one argument on the left.

⟨Infix term (abstract syntax tree) 922⟩ ≡
 InfixTermPtr = ↑*InfixTermObj*;
 InfixTermObj = **object** (*TermExpressionObj*)
 nFunctorSymbol: *integer*;
 nLeftArgs, *nRightArgs*: *PList*;
 constructor *Init*(**const** *aPos*: *Position*; *aFunctorNr*: *integer*; *aLeftArgs*, *aRightArgs*: *PList*);
 destructor *Done*; *virtual*;
 end

This code is used in section 915.

923. Constructor.

⟨Implementing term AST 917⟩ +≡
constructor *InfixTermObj*.Init(**const** *aPos*: *Position*;
 aFunctorNr: *integer*;
 aLeftArgs, *aRightArgs*: *PList*);
 begin *nTermPos* ← *aPos*; *nTermSort* ← *wsInfixTerm*; *nFunctorSymbol* ← *aFunctorNr*;
 nLeftArgs ← *aLeftArgs*; *nRightArgs* ← *aRightArgs*;
 end;
destructor *InfixTermObj*.Done;
 begin *dispose*(*nLeftArgs*, *Done*); *dispose*(*nRightArgs*, *Done*);
 end;

924. Terms with arguments. This class seems to be used only internally to the `abstract_syntax.pas` module. Recalling the UML class diagram (§913), we remember there are three subclasses to this: private functor terms (which appear in Mizar when we use “`defunc F(...) = ...`”), circumfix (“bracketed”) terms, and aggregate terms (when we construct an instance of a structure).

```

⟨Terms with arguments (abstract syntax tree) 924⟩ ≡
  TermWithArgumentsPtr = ↑TermWithArgumentsObj;
  TermWithArgumentsObj = object (TermExpressionObj)
    nArgs: PList;
    constructor Init(const aPos: Position; aKind: TermSort; aArgs: PList);
    destructor Done; virtual;
  end

```

This code is used in section 915.

925. Constructor.

```

⟨Implementing term AST 917⟩ +≡
constructor TermWithArgumentsObj.Init(const aPos: Position; aKind: TermSort; aArgs: PList);
  begin nTermPos ← aPos; nTermSort ← aKind; nArgs ← aArgs;
  end;
destructor TermWithArgumentsObj.Done;
  begin dispose(nArgs, Done);
  end;

```

926. Circumfix terms. We can introduce different types of brackets in Mizar. For example, for groups, we have the commutator of group elements `[.x,y.]`. These “bracketed terms” are referred to as circumfix terms.

```

⟨Circumfix term (abstract syntax tree) 926⟩ ≡
  CircumfixTermPtr = ↑CircumfixTermObj;
  CircumfixTermObj = object (TermWithArgumentsObj)
    nLeftBracketSymbol, nRightBracketSymbol: integer;
    constructor Init(const aPos: Position; aLeftBracketNr, aRightBracketNr: integer; aArgs: PList);
    destructor Done; virtual;
  end

```

This code is used in section 915.

927. Constructor.

```

⟨Implementing term AST 917⟩ +≡
constructor CircumfixTermObj.Init(const aPos: Position;
                                aLeftBracketNr, aRightBracketNr: integer;
                                aArgs: PList);
  begin inherited Init(aPos, wsCircumfixTerm, aArgs); nLeftBracketSymbol ← aLeftBracketNr;
  nRightBracketSymbol ← aRightBracketNr;
  end;
destructor CircumfixTermObj.Done;
  begin dispose(nArgs, Done);
  end;

```

928. Private functor terms. We introduce private functor terms in Mizar when we have “**defpred** $F(\dots) = \dots$ ”.

```

⟨ Private functor term (abstract syntax tree) 928 ⟩ ≡
  PrivateFunctorTermPtr = ↑PrivateFunctorTermObj;
  PrivateFunctorTermObj = object (TermWithArgumentsObj)
    nFunctorIdent: integer;
    constructor Init(const aPos: Position; aFunctorIdNr: integer; aArgs: PList);
    destructor Done; virtual;
  end

```

This code is used in section 915.

929. Constructor.

```

⟨ Implementing term AST 917 ⟩ +≡
constructor PrivateFunctorTermObj.Init(const aPos: Position; aFunctorIdNr: integer; aArgs: PList);
  begin inherited Init(aPos, wsPrivateFunctorTerm, aArgs); nFunctorIdent ← aFunctorIdNr;
  end;
destructor PrivateFunctorTermObj.Done;
  begin dispose(nArgs, Done);
  end;

```

930. One-argument terms. Recalling the UML class diagram for terms (§913), we remember the class for *OneArgument* terms are either selector terms (“**the** ⟨field⟩ **of** ⟨aggregate⟩”) or forgetful functors (“**the** ⟨structure⟩ **of** ⟨aggregate⟩”).

```

⟨ One-argument term (abstract syntax tree) 930 ⟩ ≡
  OneArgumentTermPtr = ↑OneArgumentTermObj;
  OneArgumentTermObj = object (TermExpressionObj)
    nArg: TermPtr;
    constructor Init(const aPos: Position; aKind: TermSort; aArg: TermPtr);
    destructor Done; virtual;
  end

```

This code is used in section 915.

931. Constructor.

```

⟨ Implementing term AST 917 ⟩ +≡
constructor OneArgumentTermObj.Init(const aPos: Position; aKind: TermSort; aArg: TermPtr);
  begin nTermPos ← aPos; nTermSort ← aKind; nArg ← aArg;
  end;
destructor OneArgumentTermObj.Done;
  begin dispose(nArg, Done);
  end;

```

932. Selector terms. When we have an aggregate term (i.e., an instance of a structure), we want to refer to fields of the structure. This is done with selector terms. [[The selector number refers to the position in the underlying tuple of the structure instance.]]

```

⟨ Selector term (abstract syntax tree) 932 ⟩ ≡
  SelectorTermPtr = ↑SelectorTermObj;
  SelectorTermObj = object (OneArgumentTermObj)
    nSelectorSymbol: integer;
    constructor Init(const aPos: Position; aSelectorNr: integer; aArg: TermPtr);
    destructor Done; virtual;
  end

```

This code is used in section 915.

933. Constructor.

```

⟨ Implementing term AST 917 ⟩ +=
constructor SelectorTermObj.Init(const aPos: Position; aSelectorNr: integer; aArg: TermPtr);
  begin inherited Init(Apos, wsSelectorTerm, aArg); nSelectorSymbol ← aSelectorNr;
  end;
destructor SelectorTermObj.Done;
  begin dispose(nArg, Done);
  end;

```

934. Internal selector terms. An “internal selector” term refers to the case where we have in Mizar “the *⟨selector⟩*” treated as a term.

```

⟨ Internal selector term (abstract syntax tree) 934 ⟩ ≡
  InternalSelectorTermPtr = ↑InternalSelectorTermObj;
  InternalSelectorTermObj = object (TermExpressionObj)
    nSelectorSymbol: integer;
    constructor Init(const aPos: Position; aSelectorNr: integer);
  end

```

This code is used in section 915.

935. Constructor.

```

⟨ Implementing term AST 917 ⟩ +=
constructor InternalSelectorTermObj.Init(const aPos: Position; aSelectorNr: integer);
  begin nTermPos ← aPos; nTermSort ← wsInternalSelectorTerm; nSelectorSymbol ← aSelectorNr;
  end;

```

936. Aggregate terms. When we construct a new instance of a structure, well, that’s a term. Such terms are called “aggregate terms” in Mizar.

```

⟨ Aggregate term (abstract syntax tree) 936 ⟩ ≡
  AggregateTermPtr = ↑AggregateTermObj;
  AggregateTermObj = object (TermWithArgumentsObj)
    nStructSymbol: integer;
    constructor Init(const aPos: Position; aStructSymbol: integer; aArgs: PList);
    destructor Done; virtual;
  end

```

This code is used in section 915.

937. Constructor.

⟨Implementing term AST 917⟩ +≡

```
constructor AggregateTermObj.Init(const aPos: Position; aStructSymbol: integer; aArgs: PList);
  begin inherited Init(aPos, wsAggregateTerm, aArgs); nStructSymbol ← aStructSymbol;
  end;

destructor AggregateTermObj.Done;
  begin dispose(nArgs, Done);
  end;
```

938. Forgetful functors. When we have structure inheritance in Mizar, say structure *B* extends structure *A*, and we have *b* being an instance of *B*, then we can obtain “the *A*-object underlying *b*” by writing “**the A of b**”. This is an example of what Mizar calls a “forgetful functor” (which is quite the pun).

⟨Forgetful functor (abstract syntax tree) 938⟩ ≡

```
ForgetfulFunctorTermPtr = ↑ForgetfulFunctorTermObj;
ForgetfulFunctorTermObj = object (OneArgumentTermObj)
  nStructSymbol: integer;
  constructor Init(const aPos: Position; aStructSymbol: integer; aArg: TermPtr);
  destructor Done; virtual;
end
```

This code is used in section 915.

939. Constructor.

⟨Implementing term AST 917⟩ +≡

```
constructor ForgetfulFunctorTermObj.Init(const aPos: Position; aStructSymbol: integer;
  aArg: TermPtr);
  begin inherited Init(aPos, wsForgetfulFunctorTerm, aArg); nStructSymbol ← aStructSymbol;
  end;

destructor ForgetfulFunctorTermObj.Done;
  begin dispose(nArg, Done);
  end;
```

940. Internal forgetful functors. When we omit the “structure instance” *b* in a forgetful functor term — e.g., when we have “**the A**” — then we have an “internal forgetful functor” (named analogous to internal selectors).

⟨Internal forgetful functors (abstract syntax tree) 940⟩ ≡

```
InternalForgetfulFunctorTermPtr = ↑InternalForgetfulFunctorTermObj;
InternalForgetfulFunctorTermObj = object (TermExpressionObj)
  nStructSymbol: integer;
  constructor Init(const aPos: Position; aStructSymbol: integer);
end
```

This code is used in section 915.

941. Constructor.

⟨Implementing term AST 917⟩ +≡

```
constructor InternalForgetfulFunctorTermObj.Init(const aPos: Position; aStructSymbol: integer);
  begin nTermPos ← aPos; nTermSort ← wsInternalForgetfulFunctorTerm;
  nStructSymbol ← aStructSymbol;
  end;
```

942. Simple Fraenkel terms. Fraenkel terms are set-builder notation in Mizar. But “simple” Fraenkel terms occurs when we have “the set of all $\langle termexpr \rangle$ ”.

```

⟨ Fraenkel terms (abstract syntax tree) 942 ⟩ ≡
  SimpleFraenkelTermPtr = ↑SimpleFraenkelTermObj;
  SimpleFraenkelTermObj = object (TermExpressionObj)
    nPostqualification: PList; { of segments }
    nSample: TermPtr;
    constructor Init(const aPos: Position; aPostqual: PList; aSample: TermPtr);
    destructor Done; virtual;
  end ;

```

See also section 944.

This code is used in section 915.

943. Constructor.

```

⟨ Implementing term AST 917 ⟩ +≡
constructor SimpleFraenkelTermObj.Init(const aPos: Position; aPostqual: PList; aSample: TermPtr);
  begin nTermPos ← aPos; nTermSort ← wsSimpleFraenkelTerm; nPostqualification ← aPostqual;
  nSample ← aSample;
  end;
destructor SimpleFraenkelTermObj.Done;
  begin dispose(nSample, Done);
  end;

```

944. Fraenkel terms. Fraenkel terms are sets given by set-builder notation, usually they look like

$$\{f(\vec{t}) \text{ where } \vec{t} \text{ being } \vec{T} : P[\vec{t}]\}$$

This is technically a higher-order object (look, it takes a functor f and a predicate P).

```

⟨ Fraenkel terms (abstract syntax tree) 942 ⟩ +≡
  FraenkelTermPtr = ↑FraenkelTermObj;
  FraenkelTermObj = object (SimpleFraenkelTermObj)
    nFormula: FormulaPtr;
    constructor Init(const aPos: Position; aPostqual: PList; aSample: TermPtr; aFormula:
      FormulaPtr);
    destructor Done; virtual;
  end

```

945. Constructor.

```

⟨ Implementing term AST 917 ⟩ +≡
constructor FraenkelTermObj.Init(const aPos: Position;
  aPostqual: PList;
  aSample: TermPtr;
  aFormula: FormulaPtr);
  begin nTermPos ← aPos; nTermSort ← wsFraenkelTerm; nPostqualification ← aPostqual;
  nSample ← aSample; nFormula ← aFormula;
  end;
destructor FraenkelTermObj.Done;
  begin dispose(nSample, Done); dispose(nPostqualification, Done); dispose(nFormula, Done);
  end;

```

946. Qualified terms. We may wish to explicitly type cast a term (e.g., “`term qua newType`”), which is what Mizar calls a “qualified term”.

```

⟨ Qualified term (abstract syntax tree) 946 ⟩ ≡
  QualifiedTermPtr = ↑QualifiedTermObj;
  QualifiedTermObj = object (ExactlyTermObj)
    nQualification: TypePtr;
    constructor Init(const aPos: Position; aSubject: TermPtr; aType: TypePtr);
    destructor Done; virtual;
  end

```

This code is used in section 915.

947. Constructor.

```

⟨ Implementing term AST 917 ⟩ +≡
constructor QualifiedTermObj.Init(const aPos: Position; aSubject: TermPtr; aType: TypePtr);
  begin nTermPos ← aPos; nTermSort ← wsQualificationTerm; nSubject ← aSubject;
  nQualification ← aType;
  end;
destructor QualifiedTermObj.Done;
  begin dispose(nSubject, Done); dispose(nQualification, Done);
  end;

```

948. Exactly terms. This is the base class for qualified terms. It does not appear to be used anywhere outside the abstract syntax module.

```

⟨ Exactly term (abstract syntax tree) 948 ⟩ ≡
  ExactlyTermPtr = ↑ExactlyTermObj;
  ExactlyTermObj = object (TermExpressionObj)
    nSubject: TermPtr;
    constructor Init(const aPos: Position; aSubject: TermPtr);
    destructor Done; virtual;
  end

```

This code is used in section 915.

949. Constructor.

```

⟨ Implementing term AST 917 ⟩ +≡
constructor ExactlyTermObj.Init(const aPos: Position; aSubject: TermPtr);
  begin nTermPos ← aPos; nTermSort ← wsExactlyTerm; nSubject ← aSubject;
  end;
destructor ExactlyTermObj.Done;
  begin dispose(nSubject, Done);
  end;

```

950. Choice terms. This refers to “the $\langle type \rangle$ ” terms. It is a “global choice term” of sorts, except it “operates” on soft types instead of arbitrary predicates.

```

< Choice term (abstract syntax tree) 950 > ≡
  ChoiceTermPtr = ↑ChoiceTermObj;
  ChoiceTermObj = object (TermExpressionObj)
    nChoiceType: TypePtr;
    constructor Init(const aPos: Position; aType: TypePtr);
    destructor Done; virtual;
end

```

This code is used in section 915.

951. Constructor.

```

< Implementing term AST 917 > +≡
constructor ChoiceTermObj.Init(const aPos: Position; aType: TypePtr);
  begin nTermPos ← aPos; nTermSort ← wsGlobalChoiceTerm; nChoiceType ← aType;
  end;
destructor ChoiceTermObj.Done;
  begin dispose(nChoiceType, Done);
  end;

```

952. It terms. When we define a new mode [type] or functors [terms], Mizar introduces an anaphoric keyword “it” referring to an example of the mode (resp., to the term being defined). Here I borrow the scary phrase “anaphoric” from Lisp macros, so blame Paul Graham for this pretentiousness.

```

< “It” term (abstract syntax tree) 952 > ≡
  ItTermPtr = ↑ItTermObj;
  ItTermObj = object (TermExpressionObj)
    constructor Init(const aPos: Position);
end

```

This code is used in section 915.

953. Constructor.

```

< Implementing term AST 917 > +≡
constructor ItTermObj.Init(const aPos: Position);
  begin nTermPos ← aPos; nTermSort ← wsItTerm;
  end;

```

954. Incorrect terms. Generically, when we run into an error of some kind, we represent the term with an *Incorrect* term instance. This will allow Mizar to continue working when the user goofed.

```

< Incorrect term (abstract syntax tree) 954 > ≡
  IncorrectTermPtr = ↑IncorrectTermObj;
  IncorrectTermObj = object (TermExpressionObj)
    constructor Init(const aPos: Position);
end

```

This code is used in section 915.

955. Constructor.

```

< Implementing term AST 917 > +≡
constructor IncorrectTermObj.Init(const aPos: Position);
  begin nTermPos ← aPos; nTermSort ← wsErrorTerm;
  end;

```

Section 20.2. TYPES (ABSTRACT SYNTAX TREE)

956. The grammar for Mizar types looks like:

```

Type-Expression = "(" Radix-Type ")"
| Adjective-Cluster Type-Expression
| Radix-Type .
Structure-Type-Expression =
  "(" Structure-Symbol ["over" Term-Expression-List] ")"
| Adjective-Cluster Structure-Symbol [ "over" Term-Expression-List ].
Radix-Type = Mode-Symbol [ "of" Term-Expression-List ]
| Structure-Symbol [ "over" Term-Expression-List ] .
Type-Expression-List = Type-Expression { "," Type-Expression } .

```

So there are several main sources of modes [types]: structures, primitive types (like “set” and “object”), and affixing adjectives to types.

For readers who are unfamiliar with types in Mizar, they are “soft types”. What does this mean? Well, we refer the reader to Free Wiedijk’s “Mizar’s Soft Type System” (in K. Schneider and J. Brandt, eds., *Theorem Proving in Higher Order Logics. TPHOLs 2007*, Springer, [doi:10.1007/978-3-540-74591-4_28](https://doi.org/10.1007/978-3-540-74591-4_28)). Essentially, a type ascription in Mizar of the form “for x being Foo st P[x] holds Q[x]”, this is equivalent to Foo being a unary predicate and the formula in first-order logic is “ $\forall x. \text{Foo}[x] \wedge Q[x] \implies P[x]$ ”.

957. We have an abstract base class for types.

```

⟨ Abstract base class for types 957 ⟩ ≡
  TypeSort = (wsErrorType, wsStandardType, wsStructureType, wsClusteredType, wsReservedDscrType);
  { Initial structures }
  TypePtr = ↑TypeExpressionObj;
  TypeExpressionObj = object (MObject)
    nTypeSort: TypeSort;
    nTypePos: Position;
  end

```

This code is used in section 897.

958. **Radix type.** A “radix type” refers to any type of the form “⟨RadixType⟩ of T_1, \dots, T_n ”. This usually appears when defining a new expandable mode, where we have:

“mode ⟨Expandable Mode⟩ is ⟨Adjective₁⟩ ... ⟨Adjective_n⟩ ⟨Radix Type⟩”

This appears to be used only in definitions.

```

⟨ Classes for type (abstract syntax tree) 958 ⟩ ≡
  { Types }
  RadixTypePtr = ↑RadixTypeObj;
  RadixTypeObj = object (TypeExpressionObj)
    nArgs: PList; { of }
    constructor Init(const aPos: Position; aKind: TypeSort; aArgs: PList);
    destructor Done; virtual;
  end ;

```

See also sections 960, 962, 964, and 966.

This code is used in section 897.

959. Constructor.

⟨Implementing type AST 959⟩ ≡
constructor *RadixTypeObj.Init*(**const** *aPos*: *Position*; *aKind*: *TypeSort*; *aArgs*: *PList*);
 begin *nTypePos* ← *aPos*; *nTypeSort* ← *aKind*; *nArgs* ← *aArgs*;
 end;
destructor *RadixTypeObj.Done*;
 begin *dispose*(*nArgs*, *Done*);
 end;

See also sections 961, 963, 965, and 967.

This code is used in section 896.

960. Standard type. When we want to refer to an expandable mode in a Mizar formula, then it is represented by a “standard type”. This contrasts it with “clustered types” (i.e., a type stacked with adjectives) and “structure types”.

⟨Classes for type (abstract syntax tree) 958⟩ +≡
 StandardTypePtr = ↑*StandardTypeObj*;
 StandardTypeObj = **object** (*RadixTypeObj*)
 nModeSymbol: *integer*;
 constructor *Init*(**const** *aPos*: *Position*; *aModeSymbol*: *integer*; *aArgs*: *PList*);
 destructor *Done*; *virtual*;
 end ;

961. Constructor.

⟨Implementing type AST 959⟩ +≡
constructor *StandardTypeObj.Init*(**const** *aPos*: *Position*; *aModeSymbol*: *integer*; *aArgs*: *PList*);
 begin *inherited Init*(*aPos*, *wsStandardType*, *aArgs*); *nModeSymbol* ← *aModeSymbol*;
 end;
destructor *StandardTypeObj.Done*;
 begin *inherited Done*;
 end;

962. Structure type. When we define a new structure, we are really introducing a new type. [[The *aArgs* tracks its parent structures and parameter types.]] The structure type extends the *RadixType* class because *RadixType* instances can be “stacked with adjectives”.

⟨Classes for type (abstract syntax tree) 958⟩ +≡
 StructTypePtr = ↑*StructTypeObj*;
 StructTypeObj = **object** (*RadixTypeObj*)
 nStructSymbol: *integer*;
 constructor *Init*(**const** *aPos*: *Position*; *aStructSymbol*: *integer*; *aArgs*: *PList*);
 destructor *Done*; *virtual*;
 end ;

963. Constructor.

⟨Implementing type AST 959⟩ +≡
constructor *StructTypeObj.Init*(**const** *aPos*: *Position*; *aStructSymbol*: *integer*; *aArgs*: *PList*);
 begin *inherited Init*(*aPos*, *wsStructureType*, *aArgs*); *nStructSymbol* ← *aStructSymbol*;
 end;
destructor *StructTypeObj.Done*;
 begin *inherited Done*;
 end;

964. Clustered type. The clustered type describes the situation where we accumulate *aCluster* of adjectives atop *aType*.

```

⟨ Classes for type (abstract syntax tree) 958 ⟩ +≡
  ClusteredTypePtr = ↑ClusteredTypeObj;
  ClusteredTypeObj = object (TypeExpressionObj)
    nAdjectiveCluster: PList;
    nType: TypePtr;
    constructor Init(const aPos: Position; aCluster: PList; aType: TypePtr);
    destructor Done; virtual;
end ;

```

965. Constructor.

```

⟨ Implementing type AST 959 ⟩ +≡
constructor ClusteredTypeObj.Init(const aPos: Position; aCluster: PList; aType: TypePtr);
  begin nTypePos ← aPos; nTypeSort ← wsClusteredType; nAdjectiveCluster ← aCluster;
  nType ← aType;
end;
destructor ClusteredTypeObj.Done;
  begin dispose(nAdjectiveCluster, Done); dispose(nType, Done);
end;

```

966. Incorrect type. We want Mizar to be resilient against typing errors, so we have an *IncorrectType* node for the syntax tree. The alternative would be to crash upon error.

```

⟨ Classes for type (abstract syntax tree) 958 ⟩ +≡
  IncorrectTypePtr = ↑IncorrectTypeObj;
  IncorrectTypeObj = object (TypeExpressionObj)
    constructor Init(const aPos: Position);
end

```

967. Constructor.

```

⟨ Implementing type AST 959 ⟩ +≡
constructor IncorrectTypeObj.Init(const aPos: Position);
  begin nTypePos ← aPos; nTypeSort ← wsErrorType;
end;

```

Section 20.3. FORMULAS (ABSTRACT SYNTAX TREE)

968. We have an abstract base class for formulas.

(Abstract base class for formulas 968) \equiv

```

FormulaSort = (wsErrorFormula, wsThesis, wsContradiction, wsRightSideOfPredicativeFormula,
wsPredicativeFormula, wsMultiPredicativeFormula, wsPrivatePredicateFormula,
wsAttributiveFormula, wsQualifyingFormula, wsUniversalFormula, wsExistentialFormula,
wsNegatedFormula, wsConjunctiveFormula, wsDisjunctiveFormula, wsConditionalFormula,
wsBiconditionalFormula, wsFlexaryConjunctiveFormula, wsFlexaryDisjunctiveFormula);
FormulaPtr =  $\uparrow$ FormulaExpressionObj;
FormulaExpressionObj = object (MObject)
  nFormulaSort: FormulaSort;
  nFormulaPos: Position;
end

```

This code is used in section 897.

969. The syntax for Mizar formulas looks like:

```

Formula-Expression = "(" Formula-Expression ")"
| Atomic-Formula-Expression
| Quantified-Formula-Expression
| Formula-Expression "&" Formula-Expression
| Formula-Expression "&" "." "&" Formula-Expression
| Formula-Expression "or" Formula-Expression
| Formula-Expression "or" "." "or" Formula-Expression
| Formula-Expression "implies" Formula-Expression
| Formula-Expression "iff" Formula-Expression
| "not" Formula-Expression
| "contradiction"
| "thesis" .
Atomic-Formula-Expression =
  [Term-Expression-List] [("does" | "do") "not"] Predicate-Symbol [Term-Expression-List]
  { [("does" | "do") "not"] Predicate-Symbol Term-Expression-List }
| Predicate-Identifier "[" [ Term-Expression-List ] "]"
| Term-Expression "is" Adjective { Adjective }
| Term-Expression "is" Type-Expression .
Quantified-Formula-Expression =
  "for" Qualified-Variables
  [ "st" Formula-Expression ]
  ( "holds" Formula-Expression | Quantified-Formula-Expression )
| "ex" Qualified-Variables "st" Formula-Expression .

```

970. Right-side of predicative formula.

⟨Classes for formula (abstract syntax tree) 970⟩ ≡
 { Formulas }
RightSideOfPredicativeFormulaPtr = \uparrow *RightSideOfPredicativeFormulaObj*;
RightSideOfPredicativeFormulaObj = **object** (*FormulaExpressionObj*)
 nPredNr: integer;
 nRightArgs: PList;
 constructor *Init*(**const** *aPos*: Position; *aPredNr*: integer; *aRightArgs*: PList);
 destructor *Done*; virtual;
end

See also sections 972, 974, 976, 978, 980, 982, 984, 986, 988, 990, 992, 994, 996, 998, 1000, 1002, 1004, 1006, and 1008.

This code is used in section 897.

971. Constructor.

⟨Implementing formula AST 971⟩ ≡
constructor *RightSideOfPredicativeFormulaObj.Init*(**const** *aPos*: Position;
 aPredNr: integer;
 aRightArgs: PList);
begin *nFormulaPos* \leftarrow *aPos*; *nFormulaSort* \leftarrow *wsRightSideOfPredicativeFormula*;
 nPredNr \leftarrow *aPredNr*; *nRightArgs* \leftarrow *aRightArgs*;
end;
destructor *RightSideOfPredicativeFormulaObj.Done*;
begin *dispose*(*nRightArgs*, *Done*);
end;

See also sections 973, 975, 977, 979, 981, 983, 985, 987, 989, 991, 993, 995, 997, 999, 1001, 1003, 1005, 1007, and 1009.

This code is used in section 896.

972. Predicative formula. A “predicative” formula refers to a formula involving predicates. A predicate will have a list of terms \vec{t} it expects as arguments, as well as two numbers ℓ, r such that t_1, \dots, t_ℓ are the arguments to its left, and $t_{\ell+1}, \dots, t_{\ell+r}$ are on the right. When $\ell = 0$, all arguments are on the right; and when $r = 0$, all arguments are on the left.

⟨Classes for formula (abstract syntax tree) 970⟩ +≡
PredicativeFormulaPtr = \uparrow *PredicativeFormulaObj*;
PredicativeFormulaObj = **object** (*RightSideOfPredicativeFormulaObj*)
 nLeftArgs: PList;
 constructor *Init*(**const** *aPos*: Position; *aPredNr*: integer; *aLeftArgs*, *aRightArgs*: PList);
 destructor *Done*; virtual;
end

973. Constructor.

⟨Implementing formula AST 971⟩ +≡
constructor *PredicativeFormulaObj.Init*(**const** *aPos*: Position;
 aPredNr: integer;
 aLeftArgs, *aRightArgs*: PList);
begin *nFormulaPos* \leftarrow *aPos*; *nFormulaSort* \leftarrow *wsPredicativeFormula*; *nPredNr* \leftarrow *aPredNr*;
 nLeftArgs \leftarrow *aLeftArgs*; *nRightArgs* \leftarrow *aRightArgs*;
end;
destructor *PredicativeFormulaObj.Done*;
begin *dispose*(*nLeftArgs*, *Done*); *dispose*(*nRightArgs*, *Done*);
end;

974. Multi-predicative formula. The Working Mathematician writes things like “ $1 \leq i \leq \|T\|$ ” and Mizar wants to support this. Multi-predicative formulas are of this form “ $1 \leq i \leq \|T\|$ ”. This occurs in VECTSP13, for example.

```

⟨ Classes for formula (abstract syntax tree) 970 ⟩ +=
  MultiPredicativeFormulaPtr = ↑MultiPredicativeFormulaObj;
  MultiPredicativeFormulaObj = object (FormulaExpressionObj)
    nScraps: PList;
    constructor Init(const aPos: Position; aScraps: PList);
    destructor Done; virtual;
end

```

975. Constructor.

```

⟨ Implementing formula AST 971 ⟩ +=
constructor MultiPredicativeFormulaObj.Init(const aPos: Position; aScraps: PList);
  begin nFormulaPos ← aPos; nFormulaSort ← wsMultiPredicativeFormula; nScraps ← aScraps;
  end;
destructor MultiPredicativeFormulaObj.Done;
  begin dispose(nScraps, Done);
  end;

```

976. Attributive formula. As part of Mizar’s soft type system, we can use attributes (adjectives) to form a formula like “ $\langle term \rangle$ is $\langle adjective \rangle$ ”. We can stack multiple adjectives in an attributive formula.

```

⟨ Classes for formula (abstract syntax tree) 970 ⟩ +=
  AttributiveFormulaPtr = ↑AttributiveFormulaObj;
  AttributiveFormulaObj = object (FormulaExpressionObj)
    nSubject: TermPtr;
    nAdjectives: PList;
    constructor Init(const aPos: Position; aSubject: TermPtr; aAdjectives: PList);
    destructor Done; virtual;
end

```

977. Constructor.

```

⟨ Implementing formula AST 971 ⟩ +=
constructor AttributiveFormulaObj.Init(const aPos: Position; aSubject: TermPtr; aAdjectives: PList);
  begin nFormulaPos ← aPos; nFormulaSort ← wsAttributiveFormula; nSubject ← aSubject;
  nAdjectives ← aAdjectives;
  end;
destructor AttributiveFormulaObj.Done;
  begin dispose(nSubject, Done); dispose(nAdjectives, Done);
  end;

```

978. Private predicative formula. When we have “**defpred** P[...] **means** ...” in Mizar, we refer to “P” as a private predicate. It is represented in the abstract syntax tree as a private predicative formula object.

```

⟨Classes for formula (abstract syntax tree) 970⟩ +≡
  PrivatePredicativeFormulaPtr = ↑PrivatePredicativeFormulaObj;
  PrivatePredicativeFormulaObj = object (FormulaExpressionObj)
    nPredIdNr: integer;
    nArgs: PList;
    constructor Init(const aPos: Position; aPredIdNr: integer; aArgs: PList);
    destructor Done; virtual;
end

```

979. Constructor.

```

⟨Implementing formula AST 971⟩ +≡
constructor PrivatePredicativeFormulaObj.Init(const aPos: Position;
    aPredIdNr: integer;
    aArgs: PList);
  begin nFormulaPos ← aPos; nFormulaSort ← wsPrivatePredicateFormula; nPredIdNr ← aPredIdNr;
  nArgs ← aArgs;
end;
destructor PrivatePredicativeFormulaObj.Done;
  begin dispose(nArgs, Done);
end;

```

980. Qualifying formula. Using Mizar’s soft type system, we may have formulas of the form “⟨term⟩ is ⟨type⟩”. These are referred to as “qualifying formulas”, at least when discussing the abstract syntax tree.

```

⟨Classes for formula (abstract syntax tree) 970⟩ +≡
  QualifyingFormulaPtr = ↑QualifyingFormulaObj;
  QualifyingFormulaObj = object (FormulaExpressionObj)
    nSubject: TermPtr;
    nType: TypePtr;
    constructor Init(const aPos: Position; aSubject: TermPtr; aType: TypePtr); y
    destructor Done; virtual;
end

```

981. Constructor.

```

⟨Implementing formula AST 971⟩ +≡
constructor QualifyingFormulaObj.Init(const aPos: Position; aSubject: TermPtr; aType: TypePtr);
  begin nFormulaPos ← aPos; nFormulaSort ← wsQualifyingFormula; nSubject ← aSubject;
  nType ← aType;
end;
destructor QualifyingFormulaObj.Done;
  begin dispose(nSubject, Done); dispose(nType, Done);
end;

```

982. Negative formula. Now we can proceed with the familiar formulas in first-order logic. Negative formulas are of the form $\neg\varphi$ for some formula φ .

```

⟨ Classes for formula (abstract syntax tree) 970 ⟩ +=
  NegativeFormulaPtr = ↑NegativeFormulaObj;
  NegativeFormulaObj = object (FormulaExpressionObj)
    nArg: FormulaPtr;
    constructor Init(const aPos: Position; aArg: FormulaPtr);
    destructor Done; virtual;
end

```

983. Constructor.

```

⟨ Implementing formula AST 971 ⟩ +=
constructor NegativeFormulaObj.Init(const aPos: Position; aArg: FormulaPtr);
  begin nFormulaPos ← aPos; nFormulaSort ← wsNegatedFormula; nArg ← aArg;
  end;
destructor NegativeFormulaObj.Done;
  begin dispose(nArg, Done);
  end;

```

984. Binary arguments formula. We have a class describing formulas involving binary logical connectives. We will extend it to describe conjunctive formulas, disjunctive formulas, conditionals, biconditionals, etc.

```

⟨ Classes for formula (abstract syntax tree) 970 ⟩ +=
  BinaryFormulaPtr = ↑BinaryArgumentsFormula;
  BinaryArgumentsFormula = object (FormulaExpressionObj)
    nLeftArg, nRightArg: FormulaPtr;
    constructor Init(const aPos: Position; aLeftArg, aRightArg: FormulaPtr);
    destructor Done; virtual;
end

```

985. Constructor.

```

⟨ Implementing formula AST 971 ⟩ +=
constructor BinaryArgumentsFormula.Init(const aPos: Position; aLeftArg, aRightArg: FormulaPtr);
  begin nFormulaPos ← aPos; nLeftArg ← aLeftArg; nRightArg ← aRightArg;
  end;
destructor BinaryArgumentsFormula.Done;
  begin dispose(nLeftArg, Done); dispose(nRightArg, Done);
  end;

```

986. Conjunctive formula. A conjunctive formula looks like $\varphi \wedge \psi$ where φ and ψ are logical formulas.

```

⟨ Classes for formula (abstract syntax tree) 970 ⟩ +=
  ConjunctiveFormulaPtr = ↑ConjunctiveFormulaObj;
  ConjunctiveFormulaObj = object (BinaryArgumentsFormula)
    constructor Init(const aPos: Position; aLeftArg, aRightArg: FormulaPtr);
end

```

987. Constructor.

⟨Implementing formula AST 971⟩ +≡
constructor *ConjunctiveFormulaObj*.Init(**const** *aPos*: *Position*; *aLeftArg*, *aRightArg*: *FormulaPtr*);
begin *inherited Init*(*aPos*, *aLeftArg*, *aRightArg*); *nFormulaSort* ← *wsConjunctiveFormula*;
end;

988. Disjunctive formula. Disjunctive formulas look like $\varphi \vee \psi$ where φ and ψ are formulas.

⟨Classes for formula (abstract syntax tree) 970⟩ +≡
DisjunctiveFormulaPtr = \uparrow *DisjunctiveFormulaObj*;
DisjunctiveFormulaObj = **object** (*BinaryArgumentsFormula*)
constructor *Init*(**const** *aPos*: *Position*; *aLeftArg*, *aRightArg*: *FormulaPtr*);
end

989. Constructor.

⟨Implementing formula AST 971⟩ +≡
constructor *DisjunctiveFormulaObj*.Init(**const** *aPos*: *Position*;
aLeftArg, *aRightArg*: *FormulaPtr*);
begin *inherited Init*(*aPos*, *aLeftArg*, *aRightArg*); *nFormulaSort* ← *wsDisjunctiveFormula*;
end;

990. Conditional formula. Conditional formulas look like $\varphi \implies \psi$ where φ and ψ are formulas.

⟨Classes for formula (abstract syntax tree) 970⟩ +≡
ConditionalFormulaPtr = \uparrow *ConditionalFormulaObj*;
ConditionalFormulaObj = **object** (*BinaryArgumentsFormula*)
constructor *Init*(**const** *aPos*: *Position*; *aLeftArg*, *aRightArg*: *FormulaPtr*);
end

991. Constructor.

⟨Implementing formula AST 971⟩ +≡
constructor *ConditionalFormulaObj*.Init(**const** *aPos*: *Position*; *aLeftArg*, *aRightArg*: *FormulaPtr*);
begin *inherited Init*(*aPos*, *aLeftArg*, *aRightArg*); *nFormulaSort* ← *wsConditionalFormula*;
end;

992. Biconditional formula. Biconditional formulas look like $\varphi \iff \psi$ where φ and ψ are formulas.

⟨Classes for formula (abstract syntax tree) 970⟩ +≡
BiconditionalFormulaPtr = \uparrow *BiconditionalFormulaObj*;
BiconditionalFormulaObj = **object** (*BinaryArgumentsFormula*)
constructor *Init*(**const** *aPos*: *Position*; *aLeftArg*, *aRightArg*: *FormulaPtr*);
end

993. Constructor.

⟨Implementing formula AST 971⟩ +≡
constructor *BiconditionalFormulaObj*.Init(**const** *aPos*: *Position*; *aLeftArg*, *aRightArg*: *FormulaPtr*);
begin *inherited Init*(*aPos*, *aLeftArg*, *aRightArg*); *nFormulaSort* ← *wsBiconditionalFormula*;
end;

994. Flexary Conjunctive formula. Flexary conjunctive formulas are unique to Mizar, though the Working Mathematician would recognize them as “just a bunch of conjunctions”. These look like $\varphi[1] \wedge \dots \wedge \varphi[n]$ where $\varphi[i]$ is a formula parametrized by a natural number i .

```

< Classes for formula (abstract syntax tree) 970 > +≡
  FlexaryConjunctiveFormulaPtr = ↑FlexaryConjunctiveFormulaObj;
  FlexaryConjunctiveFormulaObj = object (BinaryArgumentsFormula)
    constructor Init(const aPos: Position; aLeftArg, aRightArg: FormulaPtr);
  end

```

995. Constructor.

```

< Implementing formula AST 971 > +≡
constructor FlexaryConjunctiveFormulaObj.Init(const aPos: Position;
                                              aLeftArg, aRightArg: FormulaPtr);
begin inherited Init(aPos, aLeftArg, aRightArg); nFormulaSort ← wsFlexaryConjunctiveFormula;
end;

```

996. Flexary Disjunctive formula. Flexary disjunctive formulas are unique to Mizar, though the Working Mathematician would recognize them as “just a bunch of disjunctions”. These look like $\varphi[1] \vee \dots \vee \varphi[n]$ where $\varphi[i]$ is a formula parametrized by a natural number i .

```

< Classes for formula (abstract syntax tree) 970 > +≡
  FlexaryDisjunctiveFormulaPtr = ↑FlexaryDisjunctiveFormulaObj;
  FlexaryDisjunctiveFormulaObj = object (BinaryArgumentsFormula)
    constructor Init(const aPos: Position; aLeftArg, aRightArg: FormulaPtr);
  end

```

997. Constructor.

```

< Implementing formula AST 971 > +≡
constructor FlexaryDisjunctiveFormulaObj.Init(const aPos: Position;
                                              aLeftArg, aRightArg: FormulaPtr);
begin inherited Init(aPos, aLeftArg, aRightArg); nFormulaSort ← wsFlexaryDisjunctiveFormula;
end;

```

998. Quantified formula. First-order logic is distinguished by the use of terms and quantifying formulas over terms. We have a base class for quantified formulas. Using the Mizar soft type system, quantified variables are “qualified segments”.

```

< Classes for formula (abstract syntax tree) 970 > +≡
  QuantifiedFormulaPtr = ↑QuantifiedFormulaObj;
  QuantifiedFormulaObj = object (FormulaExpressionObj)
    nSegment: QualifiedSegmentPtr;
    nScope: FormulaPtr;
    constructor Init(const aPos: Position; aSegment: QualifiedSegmentPtr; aScope: FormulaPtr);
    destructor Done; virtual;
  end

```

999. Constructor.

⟨Implementing formula AST 971⟩ +≡

```
constructor QuantifiedFormulaObj.Init(const aPos: Position;
                                     aSegment: QualifiedSegmentPtr;
                                     aScope: FormulaPtr);
    begin nFormulaPos ← aPos; nSegment ← aSegment; nScope ← aScope;
    end;
destructor QuantifiedFormulaObj.Done;
    begin dispose(nSegment, Done); dispose(nScope, Done);
    end;
```

1000. Universal formula. When we want to describe a formula of the form “ $\forall x : T. \varphi[x]$ ” where T is a soft type and $\varphi[x]$ is a formula parametrized by x .

⟨Classes for formula (abstract syntax tree) 970⟩ +≡

```
UniversalFormulaPtr = ↑UniversalFormulaObj;
UniversalFormulaObj = object (QuantifiedFormulaObj)
    constructor Init(const aPos: Position; aSegment: QualifiedSegmentPtr; aScope: FormulaPtr);
    end
```

1001. Constructor.

⟨Implementing formula AST 971⟩ +≡

```
constructor UniversalFormulaObj.Init(const aPos: Position;
                                     aSegment: QualifiedSegmentPtr;
                                     aScope: FormulaPtr);
    begin inherited Init(aPos, aSegment, aScope); nFormulaSort ← wsUniversalFormula;
    end;
```

1002. Existential formula. The other quantified formula are existentially quantified formulas, which resemble “ $\exists x : T. \varphi[x]$ ” where T is a soft type and $\varphi[x]$ is a formula parametrized by x .

⟨Classes for formula (abstract syntax tree) 970⟩ +≡

```
ExistentialFormulaPtr = ↑ExistentialFormulaObj;
ExistentialFormulaObj = object (QuantifiedFormulaObj)
    constructor Init(const aPos: Position; aSegment: QualifiedSegmentPtr; aScope: FormulaPtr);
    end
```

1003. Constructor.

⟨Implementing formula AST 971⟩ +≡

```
constructor ExistentialFormulaObj.Init(const aPos: Position;
                                     aSegment: QualifiedSegmentPtr;
                                     aScope: FormulaPtr);
    begin inherited Init(aPos, aSegment, aScope); nFormulaSort ← wsExistentialFormula;
    end;
```

1004. Contradiction formula. The canonical contradiction \perp in Mizar is represented by the reserved keyword “contradiction”.

⟨Classes for formula (abstract syntax tree) 970⟩ +≡

```
ContradictionFormulaPtr = ↑ContradictionFormulaObj;
ContradictionFormulaObj = object (FormulaExpressionObj)
    constructor Init(const aPos: Position);
    end
```

1005. Constructor.

⟨ Implementing formula AST 971 ⟩ +≡
constructor *ContradictionFormulaObj.Init*(**const** *aPos*: *Position*);
 begin *nFormulaPos* ← *aPos*; *nFormulaSort* ← *wsContradiction*;
 end;

1006. Thesis formula. When we are in the middle of a proof, the goal or obligation left to be proven is called the “thesis”.

⟨ Classes for formula (abstract syntax tree) 970 ⟩ +≡
 ThesisFormulaPtr = ↑*ThesisFormulaObj*;
 ThesisFormulaObj = **object** (*FormulaExpressionObj*)
 constructor *Init*(**const** *aPos*: *Position*);
 end

1007. Constructor.

⟨ Implementing formula AST 971 ⟩ +≡
constructor *ThesisFormulaObj.Init*(**const** *aPos*: *Position*);
 begin *nFormulaPos* ← *aPos*; *nFormulaSort* ← *wsThesis*;
 end;

1008. Incorrect formula. We also have a node in abstract syntax trees for “incorrect” formulas.

⟨ Classes for formula (abstract syntax tree) 970 ⟩ +≡
 IncorrectFormulaPtr = ↑*IncorrectFormula*;
 IncorrectFormula = **object** (*FormulaExpressionObj*)
 constructor *Init*(**const** *aPos*: *Position*);
 end

1009. Constructor.

⟨ Implementing formula AST 971 ⟩ +≡
constructor *IncorrectFormula.Init*(**const** *aPos*: *Position*);
 begin *nFormulaPos* ← *aPos*; *nformulaSort* ← *wsErrorFormula*;
 end;

Section 20.4. WITHIN EXPRESSIONS (DEFERRED)

1010. The “first identification” process needs to track “within expressions”. You should probably come back to this section when you’ve arrived at the “first identification” unit.

```

⟨ Class for Within expression 1010 ⟩ ≡
  biStackedPtr = ↑biStackedObj;
  biStackedObj = object (MObject)
    end;
  WithinExprPtr = ↑WithinExprObj;
  WithinExprObj = object (MObject)
    nExpKind: ExpKind;
    nStackArr: array of biStackedPtr;
    nStackCnt: integer;
    constructor Init(aExpKind : ExpKind);
    destructor Done; virtual;
    function CreateExpressionsVariableLevel: biStackedPtr; virtual; { ?? }
    procedure Process_Adjective(aAttr : AdjectiveExpressionPtr); virtual;
    procedure Process_AdjectiveList(aCluster : PList); virtual;
    procedure Process_Variable(var aVar : VariablePtr); virtual;
    procedure Process_ImplicitlyQualifiedVariable(var aSegm : ImplicitlyQualifiedSegmentPtr); virtual;
    procedure Process_VariablesSegment(aSegm : QualifiedSegmentPtr); virtual;
    procedure Process_StartVariableSegment; virtual;
    procedure Process_FinishVariableSegment; virtual;
    procedure Process_Type(aTyp : TypePtr); virtual;
    procedure Process_BinaryFormula(aFrm : BinaryFormulaPtr); virtual;
    procedure Process_StartQuantifiedFormula(aFrm : QuantifiedFormulaPtr); virtual;
    procedure Process_QuantifiedFormula(aFrm : QuantifiedFormulaPtr); virtual;
    procedure Process_FinishQuantifiedFormula(aFrm : QuantifiedFormulaPtr); virtual;
    procedure Process_Formula(aFrm : FormulaPtr); virtual;

File 21

Weakly strict Mizar article

1030. The parser “eats in” a mizar article, then produces a `.wsx` (weakly strict Mizar) XML file containing the abstract syntax tree, and also a `.fmt` article containing the formats for the article.

This strategy should be familiar to anyone who has looked into compilers and interpreters: transform the abstract syntax tree into an intermediate representation, then transform the intermediate representations in various passes.

This module will transform the parse tree to an abstract syntax tree in XML format.

```

<wsmarticle.pas 1030> ≡
  <GNU License 4>
unit wsmarticle;
interface
uses mobjects, errhan, mscanner, syntax, abstract_syntax, xml_dict, xml_inout;
  <Publicly declared types in wsmarticle.pas 1032>
const
  <Publicly declared constants in wsmarticle.pas 1035>
  <Publicly declared functions in wsmarticle.pas 1033>
  <Global variables publicly declared in wsmarticle.pas 1187>
implementation
uses mizenv, mconsole, librenv, scanner, xml_parser
      mdebug, info end_mdebug;
  <Implementation for wsmarticle.pas 1034>
end .

```

1031. Exercise. We will create a class hierarchy for the abstract syntax trees for Mizar. A lot of this is boiler-plate. The reader is invited to write a couple of programs which will:

- (1) read in an EBNF-like grammar and emit the class hierarchy for its abstract syntax tree.
- (2) read in an EBNF-like grammar, and emit the class hierarchy for generating the XML for it.

After all, if you look at the sheer number of sections in this file, it’s staggeringly huge. But a lot of it is boiler-plate.

1032. <Publicly declared types in *wsmarticle.pas* 1032> ≡

This code is used in section 1030.

Section 21.1. WEAKLY STRICT TEXT PROPER

1035. Mizar provides a grammar for its syntax in the file
It uses a variant of EBNF:

/usr/local/doc/mizar/synta

- Terminal symbols are written "in quotes"
- Production rules are separated by vertical lines "|"
- Optional symbols are placed in [brackets]
- Repeated items zero or more times are placed in {braces}.
- Rules end in a period "."

We will freely quote from `syntax.txt`, rearranging the rules as needed to discuss the relevant parts of Mizar's grammar. We will write the `syntax.txt` passages in typewriter font.

We should recall the syntax for text items:

```
Text-Propor = Section { Section } .
Section = "begin" { Text-Item } .
Text-Item = Reservation
| Definitional-Item
| Registration-Item
| Notation-Item
| Theorem
| Scheme-Item
| Auxiliary-Item .
Definitional-Item = Definitional-Block ";" .
Registration-Item = Registration-Block ";" .
Theorem = "theorem" Compact-Statement .
Compact-Statement = Proposition Justification ";" .
Justification = Simple-Justification | Proof .
Auxiliary-Item = Statement | Private-Definition .
```

These are the different syntactic classes for "top-level statements" in the text (not the environment header) of a Mizar article. The interested reader can investigate the `syntax.txt` file more fully to get all the block statements in Mizar. We have already made these different kinds of blocks syntactic values of *BlockKind* earlier (§852). Now we want to be able to translate them into English. We will just skip ahead and make these different syntactic classes into values of an enumerated type.

(Publicly declared constants in `wsmarticle.pas` 1035) \equiv

```
BlockName: array [BlockKind] of string =
  ( `Text-Propor`, { blMain }
  `Now-Reasoning`, { blDiffuse }
  `Hereby-Reasoning`, { blHereby }
  `Proof`, { blProof }
  `Definitional-Block`, { blDefinition }
  `Notation-Block`, { blNotation }
  `Registration-Block`, { blRegistration }
  `Case`, { blCase }
  `Suppose`, { blSuppose }
  `Scheme-Block` { blPublicScheme } );
```

This code is used in section 1030.

1036. Class hierarchy for blocks. We can now translate the grammar for blocks into a class hierarchy. The “text proper” extends an abstract “block” statement. We will provide factory methods “*wsTextProper.NewBlock*” and “*NewItem*” for adding a new block (and item) contained within the caller “block”. We will be tracking the “kind” of block (§852), and the text proper will need to track which article it belongs to.

All the various kinds of blocks are handled with this one class: proofs, definitions, notations, registrations, cases, suppose blocks, schemes, hereby statements, and so on. However, some of these blocks have extra content which needs their own nodes in the abstract syntax tree, especially Definitions (§§1123 *et seq.*) and Registrations (§§1166 *et seq.*).

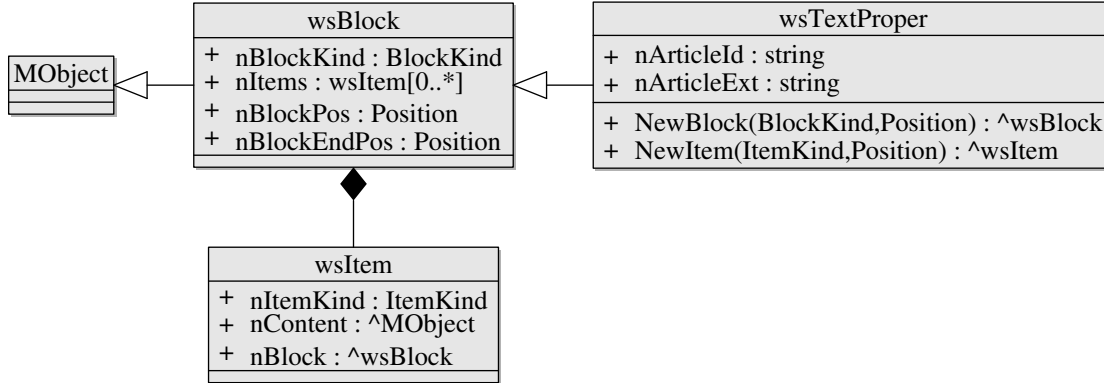

Fig. 10. UML class diagram for *wsBlock* and related classes.

It is important to stress: **wsBlock instances represent all statements which are block statements and all other statements are wsItem instances.** Looking back at the different kinds of blocks, you see that they are “block openers” and will expect to have a matching “end” statement closing it.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  wsBlockPtr = ↑wsBlock;
  wsBlock = object (MObject)
    nBlockKind: BlockKind;
    nItems: PList; { list of wsItem objects }
    nBlockPos, nBlockEndPos: Position;
    constructor Init(aBlockKind : BlockKind ; const aPos: Position);
    destructor Done; virtual;
  end ;
  ⟨ Weakly strict Item class 1040 ⟩;
  wsTextProperPtr = ↑wsTextProper;
  wsTextProper = object (wsBlock)
    nArticleID, nArticleExt: string;
    constructor Init(const aArticleID, aArticleExt: string ; const aPos: Position);
    destructor Done; virtual;
    function NewBlock(aBlockKind : BlockKind ; const aPos: Position): wsBlockPtr;
    function NewItem(aItemKind : ItemKind ; const aPos: Position): wsItemPtr;
  end ;

```

1037. Constructor. We initialize using the inherited *wsBlock* constructor (§1039). The “text proper” refers to a block which is as top-level as possible, so we construct it as a block whose kind is *blMain* located at *aPos*.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor wsTextProper.Init(const aArticleID, aArticleExt: string; const aPos: Position);
  begin inherited Init(blMain, aPos); nArticleID ← aArticleID; nArticleExt ← aArticleExt;
  end;
destructor wsTextProper.Done;
  begin inherited Done;
  end;

```

1038. Adding statements into a block. we will add a block to a “text proper”, which will then construct a block which tracks the caller as its containing block. This requires giving the kind of the newly minted block (§852).

Similarly, when constructing an item which is contained in the block, we need to pass along the item kind (§862).

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
function wsTextProper.NewBlock(aBlockKind : BlockKind ; const aPos: Position): wsBlockPtr;
  begin result ← new(WSBlockPtr, Init(aBlockKind, CurPos));
  end;
function wsTextProper.NewItem(aItemKind : ItemKind ; const aPos: Position): wsItemPtr;
  begin result ← new(wsItemPtr, Init(aItemKind, CurPos));
  end;

```

1039. Block Constructor. Curiously, the *MObject* constructor (§313) is not invoked when constructing a *wsBlock*. We will also need the position (§128) of the block in the article. The collection of items in the block is initialized to be empty.

```

constructor wsBlock.Init(aBlokKind : BlockKind ; const aPos: Position);
  begin nBlockKind ← aBlokKind; nBlockPos ← aPos; nBlockEndPos ← aPos;
  nItems ← New(PList, Init(0));
  end;
destructor wsBlock.Done;
  begin dispose(nItems, Done); inherited Done;
  end;

```

1040. Text items. An item requires its “kind” (§862) for its syntactic class.

```

⟨Weakly strict Item class 1040⟩ ≡
  wsItemPtr = ↑wsItem;
  wsItem = object (MObject)
    nItemKind: ItemKind;
    nItemPos, nItemEndPos: Position;
    nContent: PObject;
    nBlock: wsBlockPtr;
    constructor Init(aItemKind : ItemKind ; const aPos: Position);
    destructor Done; virtual;
  end ;

```

This code is used in section 1036.

1041. Constructor

⟨Implementation for `wsmarticle.pas 1034`⟩ +≡
constructor *wsItem.Init*(*aItemKind* : *ItemKind* ; **const** *aPos*: *Position*);
 begin *nItemKind* ← *aItemKind*; *nItemPos* ← *aPos*; *nItemEndPos* ← *aPos*; *nContent* ← **nil**;
 nBlock ← **nil**;
 end;
destructor *wsItem.Done*;
 begin **if** *nBlock* ≠ **nil** **then** *dispose*(*nBlock*, *Done*);
 inherited Done;
 end;

1042. Pragmas. Mizar supports pragmas (analogous to conditional compilation).

⟨Publicly declared types in `wsmarticle.pas 1032`⟩ +≡
PragmaPtr = ↑*PragmaObj*;
PragmaObj = **object** (*MObject*)
 nPragmaStr: *string*;
 constructor *Init*(*aStr* : *string*);
end ;

1043. Constructor.

⟨Implementation for `wsmarticle.pas 1034`⟩ +≡
constructor *PragmaObj.Init*(*aStr* : *string*);
 begin *nPragmaStr* ← *aStr*;
 end;

1044. Labels and propositions. A proposition is just a sentence with a label. We will need to represent both of these in our abstract syntax tree.

⟨Publicly declared types in `wsmarticle.pas 1032`⟩ +≡
LabelPtr = ↑*LabelObj*;
LabelObj = **object** (*MObject*)
 nLabelIdNr: *integer*;
 nLabelPos: *Position*;
 constructor *Init*(*aLabelId* : *integer* ; **const** *aPos*: *Position*);
end ;
PropositionPtr = ↑*PropositionObj*;
PropositionObj = **object** (*mObject*)
 nLab: *LabelPtr*;
 nSntPos: *Position*;
 nSentence: *FormulaPtr*;
 constructor *Init*(*aLab* : *LabelPtr*; *aSentence* : *FormulaPtr* ; **const** *aSntPos*: *Position*);
 destructor *Done*; *virtual*;
end ;

1045. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor LabelObj.Init(aLabelId : integer ; const aPos: Position);
  begin nLabelIdNr ← aLabelId; nLabelPos ← aPos;
  end;
constructor PropositionObj.Init(alab : LabelPtr; aSentence : FormulaPtr ; const aSntPos: Position);
  begin nLab ← aLab; nSntPos ← aSntPos; nSentence ← aSentence;
  end;
destructor PropositionObj.Done;
  begin dispose(nLab, Done); dispose(nSentence, Done);
  end;

```

1046. References. References are either local (i.e., from the file being processed) or library (i.e., from the Mizar math library). The grammar for library references is rather generous. The basic rules are that we have theorem references,

$$\langle \text{article} \rangle \text{ ":" } \langle \text{number} \rangle$$

and definition references,

$$\langle \text{article} \rangle \text{ ":"def " } \langle \text{number} \rangle$$

and scheme references,

$$\langle \text{article} \rangle \text{ ":"sch " } \langle \text{number} \rangle$$

What makes it tricky is we also allow multiple references from the same article to just add a comma followed by the theorem number

$$\langle \text{article} \rangle \text{ ":" } \langle \text{number} \rangle \{ \text{ "," } \langle \text{number} \rangle \}$$

or a comma followed by definition numbers

$$\langle \text{article} \rangle \text{ ":"def " } \langle \text{number} \rangle \{ \text{ "," "def " } \langle \text{number} \rangle \}$$

So far, so good, right? Now we can go even further, mixing theorem references and definitions references from the same article.

We recall the grammar for references:

```

⟨Reference⟩ ::= ⟨Local-Reference⟩ | ⟨Library-Reference⟩.
⟨Scheme-Reference⟩ ::= ⟨Local-Scheme-Reference⟩ | ⟨Library-Scheme-Reference⟩.
⟨Local-Reference⟩ ::= ⟨Label-Identifier⟩.
⟨Local-Scheme-Reference⟩ ::= ⟨Scheme-Identifier⟩.
⟨Library-Reference⟩ ::= ⟨Article-Name⟩ ":" (⟨Theorem-Number⟩ | "def" ⟨Definition-Number⟩)
  { \text{ "," } (⟨Theorem-Number⟩ | "def" ⟨Definition-Number⟩) } .
⟨Library-Scheme-Reference⟩ ::= ⟨Article-Name⟩ ":" "sch" ⟨Scheme-Number⟩.

```

1047. Class structure. We have an abstract “reference” class, which is either a local reference (to a label within the article) or a library reference (to some result in the MML).

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
ReferenceKind = (LocalReference, TheoremReference, DefinitionReference);
⟨Inference kinds (wsmarticle.pas) 1054⟩;
ReferencePtr = ↑ReferenceObj;
ReferenceObj = object (MObject)
  nRefSort: ReferenceKind;
  nRefPos: Position;
end;

```

1048. Local references.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  LocalReferencePtr = ↑LocalReferenceObj;
  LocalReferenceObj = object (ReferenceObj)
    nLabId: integer;
    constructor Init(aLabId : integer ; const aPos: Position);
end ;

```

1049. Constructor. The reference constructors simply populate the appropriate fields in the reference, and the position in the article's text.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor LocalReferenceObj.Init(aLabId : integer;
  const aPos: Position);
begin nRefSort ← LocalReference; nLabId ← aLabId; nRefPos ← aPos
end;

```

1050. Library references. This is the abstract class representing either theorem or definition references from an article.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  LibraryReferencePtr = ↑LibraryReferenceObj;
  LibraryReferenceObj = object (ReferenceObj)
    nArticleNr: integer;
end;

```

1051. Theorem and definition references. I am of a divided mind here. On the one hand, we can see that a *LibraryReference* is a tagged union already, and we do not need separate subclasses for theorem references and definition references. On the other hand, separate subclasses makes things easier when emitting XML for the abstract syntax tree for a Mizar article. Since it is more clear with separate subclasses, and it is better to be clear than clever, I think this design is wiser than the alternatives.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  TheoremReferencePtr = ↑TheoremReferenceObj;
  TheoremReferenceObj = object (LibraryReferenceObj)
    nTheoNr: integer;
    constructor Init(aArticleNr, aTheoNr : integer ; const aPos: Position);
end ;

  DefinitionReferencePtr = ↑DefinitionReferenceObj;
  DefinitionReferenceObj = object (LibraryReferenceObj)
    nDefNr: integer;
    constructor Init(aArticleNr, aDefNr : integer ; const aPos: Position);
end ;

```

1052. Constructor. The reference constructors simply populate the appropriate fields in the reference, and the position in the article's text.

(Implementation for `wsmarticle.pas` 1034) \equiv

```
constructor TheoremReferenceObj.Init(aArticleNr, aTheoNr : integer;
  const aPos: Position);
  begin nRefSort  $\leftarrow$  TheoremReference; nArticleNr  $\leftarrow$  aArticleNr; nTheoNr  $\leftarrow$  aTheoNr;
  nRefPos  $\leftarrow$  aPos
end;

constructor DefinitionReferenceObj.Init(aArticleNr, aDefNr : integer;
  const aPos: Position);
  begin nRefSort  $\leftarrow$  DefinitionReference; nArticleNr  $\leftarrow$  aArticleNr; nDefNr  $\leftarrow$  aDefNr;
  nRefPos  $\leftarrow$  aPos
end;
```

1053. Justifications. The grammar for justifications looks like:

```
Justification = Simple-Justification
  | Proof .

Simple-Justification = Straightforward-Justification
  | Scheme-Justification .

Proof = "proof" Reasoning "end" .

Straightforward-Justification = [ "by" References ] .

Scheme-Justification = "from" Scheme-Reference [ "(" References ")" ] .
```

Proof blocks are already represented as a *Block* object. We just need to represent the other kinds of justifications as nodes in the abstract syntax tree.

1054. The different kinds of inference, since a *Justification* is a tagged union of sorts.

(Inference kinds (wsmarticle.pas) 1054) \equiv

```
InferenceKind = (infError, infStraightforwardJustification, infSchemeJustification, infProof,
  infSkippedProof)
```

This code is used in section 1047.

1055. Class structure for justifications. The class hierarchy for justifications reflects the grammar we just discussed.

(Publicly declared types in `wsmarticle.pas` 1032) \equiv

```
JustificationPtr =  $\uparrow$ JustificationObj;
JustificationObj = object (MObject)
  nInfSort: InferenceKind;
  nInfPos: Position;
  constructor Init(aInferSort : InferenceKind ; const aPos: Position);
end ;
```

1056. Constructor.

(Implementation for `wsmarticle.pas` 1034) \equiv

```
constructor JustificationObj.Init(aInferSort : InferenceKind ; const aPos: Position);
  begin nInfSort  $\leftarrow$  aInferSort; nInfPos  $\leftarrow$  aPos;
end;
```

1057. Simple justifications. These are either “by” a list of references, or “from” a scheme.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  SimpleJustificationPtr = ↑SimpleJustificationObj;
  SimpleJustificationObj = object (JustificationObj)
    nReferences: PList;
    constructor Init(aInferSort : InferenceKind ; const aPos: Position);
    destructor Done; virtual;
  end ;

```

1058. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor SimpleJustificationObj.Init(aInferSort : InferenceKind ; const aPos: Position);
  begin inherited Init(aInferSort, aPos); nReferences ← new(PList, Init(0));
  end;
destructor SimpleJustificationObj.Done;
  begin dispose(nReferences, Done); inherited Done;
  end;

```

1059. Straightforward justification.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  StraightforwardJustificationPtr = ↑StraightforwardJustificationObj;
  StraightforwardJustificationObj = object (SimpleJustificationObj)
    nLinked: boolean;
    nLinkPos: Position;
    constructor Init(const aPos: Position; aLinked: boolean; const aLinkPos: Position);
    destructor Done; virtual;
  end ;

```

1060. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor StraightforwardJustificationObj.Init(const aPos: Position;
  aLinked: boolean;
  const aLinkPos: Position);
  begin inherited Init(infStraightforwardJustification, aPos); nLinked ← aLinked; nLinkPos ← aLinkPos;
  end;
destructor StraightforwardJustificationObj.Done;
  begin inherited Done;
  end;

```

1061. Scheme justification.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  SchemeJustificationPtr = ↑SchemeJustificationObj;
  SchemeJustificationObj = object (SimpleJustificationObj)
    nSchFileNr: integer; { 0 for schemes from current article and positive for library references }
    nSchemeIdNr: integer; { a number of a scheme for library reference nSchFileNr > 0 or a number of
      an identifier name for scheme name from current article }
    nSchemeInfPos: Position;
    constructor Init(const aPos: Position; aArticleNr, aNr: integer);
    destructor Done; virtual;
  end ;

```

1062. Constructor.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
constructor SchemeJustificationObj.Init(const aPos: Position; aArticleNr, aNr: integer);
  begin inherited Init(infSchemeJustification, aPos); nSchFileNr ← aArticleNr; nSchemeIdNr ← aNr;
    nSchemeInfPos ← aPos;
  end;

destructor SchemeJustificationObj.Done;
  begin inherited Done;
  end;
```

Section 21.2. SCHEMES

1063. The grammar for schemes looks like:

```

Scheme-Item = Scheme-Block ";" .
Scheme-Block = "scheme" Scheme-Identifier "{" Scheme-Parameters "}" ":"
  Scheme-Conclusion ["provided" Scheme-Premise {"and" Scheme-Premise}]
  ("proof" | ";") Reasoning "end" .
Scheme-Identifier = Identifier .
Scheme-Parameters = Scheme-Segment "," Scheme-Segment .
Scheme-Conclusion = Sentence .
Scheme-Premise = Proposition .
Scheme-Segment = Predicate-Segment | Functor-Segment .
Predicate-Segment =
  Predicate-Identifier {""," Predicate-Identifier} "[" [Type-Expression-List] "]" .
Predicate-Identifier = Identifier .
Functor-Segment =
  Functor-Identifier {""," Functor-Identifier} "(" [Type-Expression-List] ")" Specification .
Functor-Identifier = Identifier .

```

We begin with the abstract syntax for scheme parameters.

1064. Class hierarchy for schemes. We need “predicate segments” and “functor segments” for the second-order variable parameters to the scheme.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  SchemeSegmentKind = (PredicateSegment, FunctorSegment);
  SchemeSegmentPtr = ↑SchemeSegmentObj;
  SchemeSegmentObj = object (MObject)
    nSegmPos: Position;
    nSegmSort: SchemeSegmentKind;
    nVars: PList;
    nTypeExpList: PList;
    constructor Init(const aPos: Position; aSegmSort: SchemeSegmentKind;
      aVars, aTypeExpList: PList);
    destructor Done; virtual;
  end ;

```

1065. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor SchemeSegmentObj.Init(const aPos: Position;
  aSegmSort: SchemeSegmentKind;
  aVars, aTypeExpList: PList);
begin nSegmPos ← aPos; nSegmSort ← aSegmSort; nVars ← aVars; nTypeExpList ← aTypeExpList;
end;
destructor SchemeSegmentObj.Done;
begin dispose(nVars, Done); dispose(nTypeExpList, Done);
end;

```

1066. Segment variables for schemes. We need “predicate segments” and “functor segments” for the second-order variable parameters to the scheme.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  PredicateSegmentPtr = SchemeSegmentPtr;
  FunctorSegmentPtr = ↑FunctorSegmentObj;
  FunctorSegmentObj = object (SchemeSegmentObj)
    nSpecification: TypePtr;
    constructor Init(const aPos: Position; aVars, aTypeExpList: PList; aSpecification: TypePtr);
    destructor Done; virtual;
  end ;

```

1067. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor FunctorSegmentObj.Init(const aPos: Position;
                                   aVars, aTypeExpList: PList;
                                   aSpecification: TypePtr);
begin inherited Init(aPos, FunctorSegment, aVars, aTypeExpList); nSpecification ← aSpecification;
end;
destructor FunctorSegmentObj.Done;
begin dispose(nSpecification, Done); inherited Done;
end;

```

1068. Scheme. A *Scheme* object is the parent class of *MSScheme* objects in *first_identification.pas*. But it does not appear to be used anywhere else. This has no place in the abstract syntax tree, for example.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  SchemePtr = ↑SchemeObj;
  SchemeObj = object (MObject)
    nSchemeIdNr: integer;
    nSchemePos: Position;
    nSchemeParams: PList;
    nSchemeConclusion: FormulaPtr;
    nSchemePremises: PList;
    constructor Init(aIdNr: integer ; const aPos: Position; aParams: PList; aPrems: PList;
                    aConcl: FormulaPtr);
    destructor Done; virtual;
  end ;

```

1069. Constructor.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
constructor SchemeObj.Init(aIdNr : integer;
                           const aPos: Position;
                           aParams: PList;
                           aPremis: PList;
                           aConcl: FormulaPtr);
  begin nSchemeIdNr ← aIdNr; nSchemePos ← aPos; nSchemeParams ← aParams;
        nSchemeConclusion ← aConcl; nSchemePremises ← aPremis;
  end;

destructor SchemeObj.Done;
  begin dispose(nSchemeParams, Done); dispose(nSchemeConclusion, Done);
        dispose(nSchemePremises, Done);
  end;
```

1070. Reservations. We can “reserve” an identifier and its type, so we do not need to quantify over it for each theorem. The grammar for it:

```
Reservation = "reserve" Reservation-Segment { "," Reservation-Segment } ";" .
Reservation-Segment = Reserved-Identifiers "for" Type-Expression .
Reserved-Identifiers = Identifier { "," Identifier } .
```

The data needed for a **reserved** node in the abstract syntax tree amounts to a list of identifiers and a type.

⟨Publicly declared types in `wsmarticle.pas` 1032⟩ +≡

```
ReservationSegmentPtr = ↑ReservationSegmentObj;
ReservationSegmentObj = object (MObject)
  nIdentifiers: PList;
  nResType: TypePtr;
  constructor Init(aIdentifiers : PList; aType : TypePtr);
  destructor Done; virtual;
end ;
```

1071. Constructor.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
constructor ReservationSegmentObj.Init(aIdentifiers : PList; aType : TypePtr);
  begin nIdentifiers ← aIdentifiers; nResType ← aType;
  end;

destructor ReservationSegmentObj.Done;
  begin dispose(nIdentifiers, Done); dispose(nResType, Done);
  end;
```

Section 21.3. PRIVATE DEFINITIONS

1072. The grammar for “private definitions” (which introduces block-local or article-local terms and predicates) looks like:

```
Private-Definition = Constant-Definition
                  | Private-Functor-Definition
                  | Private-Predicate-Definition .
Constant-Definition = "set" Equating-List ";" .
Equating-List = Equating {"", " Equating" }.
Equating = Variable-Identifier "=" Term-Expression .
Private-Functor-Definition = "deffunc" Private-Functor-Pattern "=" Term-Expression ";" .
Private-Predicate-Definition = "defpred" Private-Predicate-Pattern "means" Sentence ";" .
Private-Functor-Pattern = Functor-Identifier "(" [ Type-Expression-List ] ")" .
Private-Predicate-Pattern = Predicate-Identifier "[" [Type-Expression-List ] "]" .
```

So we really only need to describe private predicates, private functors, and “constant definitions” (which introduce an abbreviation).

1073. Private functors.

```
<Publicly declared types in wsmarticle.pas 1032> +≡
  PrivateFunctorDefinitionPtr = ↑PrivateFunctorDefinitionObj;
  PrivateFunctorDefinitionObj = object (MObject)
    nFuncId: VariablePtr;
    nTypeExpList: PList;
    nTermExpr: TermPtr;
    constructor Init(aFuncId : VariablePtr; aTypeExpList : Plist; aTerm : TermPtr);
    destructor Done; virtual;
  end ;
```

1074. Constructor.

```
<Implementation for wsmarticle.pas 1034> +≡
constructor PrivateFunctorDefinitionObj.Init(aFuncId : VariablePtr; aTypeExpList : Plist;
  aTerm : TermPtr);
  begin nFuncId ← aFuncId; nTypeExpList ← aTypeExpList; nTermExpr ← aTerm;
  end;
destructor PrivateFunctorDefinitionObj.Done;
  begin dispose(nFuncId, Done); dispose(nTypeExpList, Done); dispose(nTermExpr, Done);
  end;
```

1075. Private predicates.

```
<Publicly declared types in wsmarticle.pas 1032> +≡
  PrivatePredicateDefinitionPtr = ↑PrivatePredicateDefinitionObj;
  PrivatePredicateDefinitionObj = object (MObject)
    nPredId: VariablePtr;
    nTypeExpList: PList;
    nSentence: FormulaPtr;
    constructor Init(aPredId : VariablePtr; aTypeExpList : Plist; aSnt : FormulaPtr);
    destructor Done; virtual;
  end ;
```

1076. Constructor.

⟨Implementation for `wsmarticle.pas 1034`⟩ +≡
constructor *PrivatePredicateDefinitionObj*.Init(*aPredId* : *VariablePtr*; *aTypeExpList* : *Plist*;
aSnt : *FormulaPtr*);
 begin *nPredId* ← *aPredId*; *nTypeExpList* ← *aTypeExpList*; *nSentence* ← *aSnt*;
 end;
destructor *PrivatePredicateDefinitionObj*.Done;
 begin *dispose*(*nPredId*, Done); *dispose*(*nTypeExpList*, Done); *dispose*(*nSentence*, Done);
 end;

1077. Constant definitions. These are little more than abbreviations for terms, and their implementations reflect this: they are pointers with delusions of grandeur.

⟨Publicly declared types in `wsmarticle.pas 1032`⟩ +≡
ConstantDefinitionPtr = ↑*ConstantDefinitionObj*;
ConstantDefinitionObj = **object** (*MObject*)
 nVarId: *VariablePtr*;
 nTermExpr: *TermPtr*;
 constructor Init(*aVarId* : *VariablePtr*; *aTerm* : *TermPtr*);
 destructor Done; *virtual*;
end ;

1078. Constructor.

⟨Implementation for `wsmarticle.pas 1034`⟩ +≡
constructor *ConstantDefinitionObj*.Init(*aVarId* : *VariablePtr*; *aTerm* : *TermPtr*);
 begin *nVarId* ← *aVarId*; *nTermExpr* ← *aTerm*;
 end;
destructor *ConstantDefinitionObj*.Done;
 begin *dispose*(*nVarId*, Done); *dispose*(*nTermExpr*, Done);
 end;

Section 21.4. CHANGING TYPES

1079. Each term has a soft type associated with it, but we can “reconsider” or change its type. Mizar requires a proof that the term really has the new type. The grammar for this statement:

```
Type-Changing-Statement =
  "reconsider" Type-Change-List "as" Type-ExpressionSimple-Justification ";" .
Type-Change-List =
  (Equating | Variable-Identifier) {"," (Equating | Variable-Identifier)}
```

This requires a bit of work since we really have *two* types of reconsiderations within a single reconsider statement:

- (1) “reconsider $\langle identifier \rangle$ as $\langle type \rangle$ ”
- (2) “reconsider $\langle identifier \rangle = \langle term \rangle$ as $\langle type \rangle$ ”

The trick is to represent a Type-Change-List as a list of Type-Changes. Then a Type-Change-Statement is just a Type-Change-List and a type.

1080. Class hierarchy.

```
<Publicly declared types in wsmarticle.pas 1032> +≡
TypeChangeSort = (Equating, VariableIdentifier);
TypeChangePtr = ↑TypeChangeObj;
TypeChangeObj = object (MObject)
  nTypeChangeKind: TypeChangeSort;
  nVar: VariablePtr;
  nTermExpr: TermPtr;
  constructor Init(aKind : TypeChangeSort; aVar : VariablePtr; aTerm : TermPtr);
  destructor Done; virtual;
end ;
<Example classes (wsmarticle.pas) 1083>
TypeChangingStatementPtr = ↑TypeChangingStatementObj;
TypeChangingStatementObj = object (MObject)
  nTypeChangeList: PList;
  nTypeExpr: TypePtr;
  nJustification: SimpleJustificationPtr;
  constructor Init(aTypeChangeList : PList; aTypeExpr : TypePtr;
    aJustification : SimpleJustificationPtr);
  destructor Done; virtual;
end ;
```

1081. Constructor.

(Implementation for `wsmarticle.pas` 1034) +≡
constructor *TypeChangeObj*.Init(*aKind* : *TypeChangeSort*; *aVar* : *VariablePtr*; *aTerm* : *TermPtr*);
 begin *nTypeChangeKind* ← *aKind*; *nVar* ← *aVar*; *nTermExpr* ← *aTerm*;
 end;
destructor *TypeChangeObj*.Done;
 begin *dispose*(*nVar*, *Done*);
 if *nTermExpr* ≠ **nil** **then** *dispose*(*nTermExpr*, *Done*);
 end;
 (Constructors for example statements (`wsmarticle.pas`) 1084)
constructor *TypeChangingStatementObj*.Init(*aTypeChangeList* : *PList*; *aTypeExpr* : *TypePtr*;
 aJustification : *SimpleJustificationPtr*);
 begin *nTypeChangeList* ← *aTypeChangeList*; *nTypeExpr* ← *aTypeExpr*;
 nJustification ← *aJustification*;
 end;
destructor *TypeChangingStatementObj*.Done;
 begin *dispose*(*nTypeChangeList*, *Done*); *dispose*(*nTypeExpr*, *Done*); *dispose*(*nJustification*, *Done*);
 end;

Section 21.5. PROOF STEPS

1082. Most of the proof steps are handled in generic text-item objects. But there are a few which are outside that tagged union. In particular: existential elimination (**consider** $\langle variables \rangle$ **such that** $\langle formula \rangle$), existential introduction (**take** $\langle terms \rangle$), and concluding statements (**thus** $\langle formula \rangle$).

1083. Examples, existential introduction. The proof step “take x ” transforms goals of the form $\exists x. P[x]$ into a new goal $P[x]$. The grammar for examples looks like:

Exemplification = "take" Example {"," Example} ";" .

Example = Term-Expression | Variable-Identifier "=" Term-Expression .

\langle Example classes (wsmarticle.pas) 1083 $\rangle \equiv$

```
ExamplePtr = ↑ExampleObj;
ExampleObj = object (MObject)
  nVarId: VariablePtr;
  nTermExpr: TermPtr;
  constructor Init(aVarId : VariablePtr; aTerm : TermPtr);
  destructor Done; virtual;
end ;
```

This code is used in section 1080.

1084. Constructor.

\langle Constructors for example statements (wsmarticle.pas) 1084 $\rangle \equiv$

```
constructor ExampleObj.Init(aVarId : VariablePtr; aTerm : TermPtr);
begin nVarId ← aVarId; nTermExpr ← aTerm;
end;
destructor ExampleObj.Done;
begin if nVarId ≠ nil then dispose(nVarId, Done);
if nTermExpr ≠ nil then dispose(nTermExpr, Done);
end;
```

This code is used in section 1081.

1085. Existential elimination. We continue plugging along with the statements, and existential elimination (or “choice”) statements are the next one.

Linkable-Statement = Compact-Statement

```
| Choice-Statement
| Type-Changing-Statement
| Iterative-Equality .
```

Choice-Statement = "consider" Qualified-Variables "such" ConditionsSimple-Justification ";" .

1086. \langle Publicly declared types in wsmarticle.pas 1032 $\rangle + \equiv$

```
ChoiceStatementPtr = ↑ChoiceStatementObj;
ChoiceStatementObj = object (MObject)
  nQualVars: PList;
  nConditions: PList;
  nJustification: SimpleJustificationPtr;
  constructor Init(aQualVars, aConds : PList; aJustification : SimpleJustificationPtr);
  destructor Done; virtual;
end ;
```

1087. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor ChoiceStatementObj.Init(aQualVars, aConds : PList; aJustification : SimpleJustificationPtr);
  begin nQualVars ← aQualVars; nConditions ← aConds; nJustification ← aJustification;
  end;
destructor ChoiceStatementObj.Done;
  begin dispose(nQualVars, Done); dispose(nConditions, Done); dispose(nJustification, Done);
  end;

```

1088. Conclusion statements. We recall the grammar for conclusion statements:

```

Conclusion = ( "thus" | "hence" ) ( Compact-Statement | Iterative-Equality )
           | Diffuse-Conclusion .
Diffuse-Conclusion = "thus" Diffuse-Statement | "hereby" Reasoning "end" ";" .
Iterative-Equality =
[ Label-Identifier ":" ] Term-Expression "=" Term-ExpressionSimple-Justification
                        "." Term-Expression Simple-Justification
                        { "." Term-Expression Simple-Justification } ";" .

```

NOTE: the whitespace in the Iterative-Equality rule is unimportant, but that is how Mizar users often structure them (to align the equals sign).

1089. Abstract base class.

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
RegularStatementKind = (stDiffuseStatement, stCompactStatement, stIterativeEquality);
RegularStatementPtr = ↑RegularStatementObj;
RegularStatementObj = object (MObject)
  nStatementSort: RegularStatementKind;
  nLab: LabelPtr;
  constructor Init(aStatementSort : RegularStatementKind);
  destructor Done; virtual;
end ;

```

1090. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor RegularStatementObj.Init(aStatementSort : RegularStatementKind);
  begin nStatementSort ← aStatementSort;
  end;
destructor RegularStatementObj.Done;
  begin inherited Done;
  end;

```

1091. Thus statement. The conclusion of a proof (idiomatically “thus thesis”) is always a “thus”, which Mizar calls a “diffuse statement”.

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
DiffuseStatementPtr = ↑DiffuseStatementObj;
DiffuseStatementObj = object (RegularStatementObj)
  constructor Init(aLab : LabelPtr; aStatementSort : RegularStatementKind);
  destructor Done; virtual;
end ;

```

1092. Constructor.

\langle Implementation for `wsmarticle.pas 1034` $\rangle + \equiv$
constructor *DiffuseStatementObj.Init*(*aLab* : *LabelPtr*; *aStatementSort* : *RegularStatementKind*);
 begin *inherited Init*(*stDiffuseStatement*); *nLab* \leftarrow *aLab*; *nStatementSort* \leftarrow *aStatementSort*;
 end;
destructor *DiffuseStatementObj.Done*;
 begin *dispose*(*nLab*, *Done*);
 end;

1093. Compact statements. We recall the syntax for a compact statement is:

`Compact-Statement = Proposition Justification ";" .`

\langle Publicly declared types in `wsmarticle.pas 1032` $\rangle + \equiv$
CompactStatementPtr = \uparrow *CompactStatementObj*;
CompactStatementObj = **object** (*RegularStatementObj*)
 nProp: *PropositionPtr*;
 nJustification: *JustificationPtr*;
 constructor *Init*(*aProp* : *PropositionPtr*; *aJustification* : *JustificationPtr*);
 destructor *Done*; *virtual*;
end ;

1094. Constructor.

\langle Implementation for `wsmarticle.pas 1034` $\rangle + \equiv$
constructor *CompactStatementObj.Init*(*aProp* : *PropositionPtr*; *aJustification* : *JustificationPtr*);
 begin *inherited Init*(*stCompactStatement*); *nProp* \leftarrow *aProp*; *nJustification* \leftarrow *aJustification*;
 end;
destructor *CompactStatementObj.Done*;
 begin if *nJustification* \neq **nil** **then** *dispose*(*nJustification*, *Done*);
 inherited Done;
 end;

1095. Iterative equality. Chain of equations, where we keep transforming the right-hand side until we arrive at the desired outcome.

\langle Publicly declared types in `wsmarticle.pas 1032` $\rangle + \equiv$
IterativeStepPtr = \uparrow *IterativeStepObj*;
IterativeStepObj = **object** (*MObject*)
 nIterPos: *Position*;
 nTerm: *TermPtr*;
 nJustification: *SimpleJustificationPtr*;
 constructor *Init*(**const** *aPos*: *Position*; *aTerm*: *TermPtr*; *aJustification*: *JustificationPtr*);
 destructor *Done*; *virtual*;
end ;

1096. \langle Publicly declared types in `wsmarticle.pas 1032` $\rangle + \equiv$

IterativeEqualityPtr = \uparrow *IterativeEqualityObj*;
IterativeEqualityObj = **object** (*CompactStatementObj*)
 nIterSteps: *PList*;
 constructor *Init*(*aProp* : *PropositionPtr*; *aJustification* : *JustificationPtr*; *aIters* : *PList*);
 destructor *Done*; *virtual*;
end ;

1097. Constructor.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
constructor IterativeStepObj.Init(const aPos: Position; aTerm: TermPtr; aJustification:  
    JustificationPtr);  
    begin nIterPos ← aPos; nTerm ← aTerm; nJustification ← SimpleJustificationPtr(aJustification);  
    end;  
destructor IterativeStepObj.Done;  
    begin dispose(nTerm, Done); dispose(nJustification, Done);  
    end;
```

1098. Constructor.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
constructor IterativeEqualityObj.Init(aProp: PropositionPtr; aJustification: JustificationPtr;  
    aIters: PList);  
    begin inherited Init(aProp, aJustification); nStatementSort ← stIterativeEquality; nIterSteps ← aIters;  
    end;  
destructor IterativeEqualityObj.Done;  
    begin dispose(nIterSteps, Done); inherited Done;  
    end;
```

1099. Remaining proof steps? So where are the other proof steps like `let` or `assume`? Well, these are handled as “generic text items” and use the *TextItem* class (§1040).

Section 21.6. STRUCTURES

1100. Just an aside first on “what is a structure in Mathematics?” Logic textbooks assume an *intuitive* (i.e., not formal) “finitary metatheory” following Hilbert and his famous Programme in the foundations of Mathematics. We will build a “skyscraper” atop this foundation of finitary metatheory. The first thing we do is describe a logic, the first floor in our sky scraper. This “Logic #1” is the metalogic we use to construct an axiomatic set theory, “Set Theory #2”. We use “Set Theory #2” to construct another floor, a “Logic #3”, which then builds another floor “Set Theory #4”, and so on. We can potentially iterate building as many floors as we want, but 4 is sufficient for our purposes.

We **assert** that “Set Theory #2” is the Platonic “mathematical reality”. Then “Logic #3” is the (ambient) logic we use to do Mathematics; it is purely “syntactic”, a language for expressing proofs and definitions. Mizar’s proof steps, formulas, and definitions corresponds to “Logic #3”. With it, we describe an axiomatic “Set Theory #4”, which is Tarski–Grothendieck set theory for Mizar. Sketching this situation out diagrammatically:

Set Theory #4	(Where we work) [syntactic]
Logic #3	“Object logic” (Where we write proofs) [syntactic]
Set Theory #2	“Mathematical Reality” [semantic]
Logic #1	“Metalogic”
Finitary Metatheory	

Fig. 11. Mathematical Platonism as a skyscraper.

Now, “mathematical objects” live in “Set Theory #2”. Model theory studies structures (objects in “Set Theory #2”) of theories (described in “Logic #3”). Since we “believe” that set theory “describes reality”, that means we just need to describe [“syntactic”] theories using “Set Theory #4” and their “real world occurrences” in “Set Theory #2”. (Well, this is a gloss, model theory sets up two additional floors in the skyscraper, and studies “models” of theories described using Logic #5 and Set Theory #6 in Set Theory #4 — and we pretend it describes the relationship between Set Theory #2 and the “syntactic floors” of the Mathematical skyscraper.)

How do we *syntactically* describe these “structures”? Well, we *know* they are not “first-class citizens” in Mizar, in the sense that they are not “just” a tuple. How do we know this? Gilbert Lee and Piotr Rudnicki’s “Alternative Aggregates in Mizar” (in *MKM 2007*, Springer, pp.327–341; [doi:10.1007/978-3-540-73086-6_26](https://doi.org/10.1007/978-3-540-73086-6_26)) discuss how to implement first-class structures in Mizar. This means that *technically* structures live in Logic #3. Field symbols are terms in Logic #3.

1101. Why do we need this convoluted skyscraper? Without it, how do we describe a “true” formula? We can only speak of a *provable* formula. Bourbaki’s *Theory of Sets* (I §2.2) confuses “provable” with “true” formulas (they speak of a formula being “false in a theory \mathcal{T} ” as being synonymous with the formula contradicting the axioms for a theory, and true in a theory as being synonymous for being a logical consequence from the axioms for a theory). This only matters for Mathematical Platonists. Formalists (like the author) would find this discussion muddled and nearly metaphysical, generating more heat than light.

1102. Aside: finitary metatheory, programming languages, implementing proof assistants.

How does that diagram in Figure 11 of the last section compare to the *actual implementation* of Mizar? Well, a proof assistant replaces the “finitary metatheory” with an actual programming language. Then, since only Mathematical Platonists care about the “Metalogic” and “Mathematical reality”, we jump ahead to implement Logic #3 — this is what happens in Mizar and other proof assistants: we implement a “purely formal” (purely syntactic) logic using a programming language. Curiously, this reflects Bourbaki’s approach to the foundations of Mathematics.

We should note that programming languages are strictly stronger than finitary metatheory, since programming languages are *Turing complete*. This means they support general recursion, whereas finitary metatheory supports only primitive recursive functions. For an example of a “programming language” which is equally as strong as a finitary metatheory, see Albert R. Meyer and Dennis M. Ritchie, “The complexity of loop programs” (*ACM ’67 Proc.*, 1967, [doi:10.1145/800196.806014](https://doi.org/10.1145/800196.806014)).

Is Turing completeness “too much” for a finitary metatheory? The short answer is: yes. Even restricting a Turing complete programming language is “too much” to be finitary. Gödel’s System T was developed to preserve the “constructive character” while jettisoning the “finitary character” of Hilbert’s finitary metatheory, and System T is not even Turing complete. See Kurt Gödel’s *Collected Works* (vol. II, Oxford University Press, [doi:10.1093/oso/9780195147216.001.0001](https://doi.org/10.1093/oso/9780195147216.001.0001), 1989; viz., pp. 245–247) for his discussion of System T. The interested reader should consult David A. Turner’s “Elementary strong functional programming” (in *Int. Symp. on Funct. Program. Lang. in Educ.*, eds P.H. Hartel and R. Plasmeijer, Springer, pages 1–13, [doi:10.1007/3-540-60675-0_35](https://doi.org/10.1007/3-540-60675-0_35)) for how to obtain System T by restricting any statically typed functional programming language.

1103. Grammar for structures. We can recall the syntax for structures and fields:

```
Structure-Definition =
  "struct" [ "(" Ancestors ")" ] Structure-Symbol [ "over" Loci ] "(" Fields ")" ";" .
Ancestors = Structure-Type-Expression { "," Structure-Type-Expression } .
Structure-Symbol = Symbol .
Loci = Locus { "," Locus } .
Fields = Field-Segment { "," Field-Segment } .
Locus = Variable-Identifier .
Variable-Identifier = Identifier .
Field-Segment = Selector-Symbol { "," Selector-Symbol } Specification .
Selector-Symbol = Symbol .
```

1104. Field symbol. A “field symbol” refers to the identifier used for a field in a structure, but not its type.

```
<Publicly declared types in wsmarticle.pas 1032> +≡
  FieldSymbolPtr = ↑FieldSymbolObj;
  FieldSymbolObj = object (MObject)
    nFieldPos: Position;
    nFieldSymbol: integer;
    constructor Init(const aPos: Position; aFieldSymbNr: integer);
  end ;
```

1105. Constructor.

```
<Implementation for wsmarticle.pas 1034> +≡
constructor FieldSymbolObj.Init(const aPos: Position; aFieldSymbNr: integer);
  begin nFieldPos ← aPos; nFieldSymbol ← aFieldSymbNr;
end;
```

1106. Field segment. A field segment refers to a list of 1 or more field symbols, and the associated type it has.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  FieldSegmentPtr = ↑FieldSegmentObj;
  FieldSegmentObj = object (MObject)
    nFieldSegmPos: Position;
    nFields: PList;
    nSpecification: TypePtr;
    constructor Init(const aPos: Position; aFields: PList; aSpec: TypePtr);
    destructor Done; virtual;
  end ;

```

1107. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor FieldSegmentObj.Init(const aPos: Position; aFields: PList; aSpec: TypePtr);
  begin nFieldSegmPos ← aPos; nFields ← aFields; nSpecification ← aSpec;
  end;
destructor FieldSegmentObj.Done;
  begin dispose(nFields, Done); dispose(nSpecification, Done);
  end;

```

1108. Locus. A “locus” refers to a term or type parametrizing a definition.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  LocusPtr = ↑LocusObj;
  LocusObj = object (MObject)
    nVarId: integer;
    nVarIdPos: Position;
    constructor Init(const aPos: Position; aIdentNr: integer);
  end ;

```

1109. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor LocusObj.Init(const aPos: Position; aIdentNr: integer);
  begin nVarId ← aIdentNr; nVarIdPos ← aPos;
  end;

```

1110. Structure definition. Finally, structures are finite maps from selectors to terms, with structure inheritance thrown into the mix. They may be defined “**over**” a finite list of types (e.g., a module structure is “**over**” a ring). Note that we need to first introduce “patterns” before describing the structure definition, since “patterns” are needed in definitions.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  ⟨ Pattern objects (wsmarticle.pas) 1113 ⟩
  StructureDefinitionPtr = ↑StructureDefinitionObj;
  StructureDefinitionObj = object (MObject)
    nStrPos: Position;
    nAncestors: PList;
    nDefStructPattern: ModePatternPtr;
    nSgmFields: PList;
    constructor Init(const aPos: Position; aAncestors: PList; aStructSymb: integer;
      aOverArgs: PList; aFields: PList);
    destructor Done; virtual;
  end ;

```

1111. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor StructureDefinitionObj.Init(const aPos: Position; aAncestors: PList;
  aStructSymb: integer; aOverArgs: PList; aFields: PList);
  begin nStrPos ← aPos; nAncestors ← aAncestors;
    nDefStructPattern ← new(ModePatternPtr, Init(aPos, aStructSymb, aOverArgs));
    nDefStructPattern.↑.nPatternSort ← itDefStruct; nSgmFields ← aFields;
  end;
destructor StructureDefinitionObj.Done;
  begin dispose(nAncestors, Done); dispose(nDefStructPattern, Done); dispose(nSgmFields, Done);
  end;

```

Section 21.7. PATTERNS

1112. A “*Pattern*” in Mizar is a format with the type information for all the arguments around a term. The notion of a “*Pattern*” also refers to the definiendum of a definition. The syntax of patterns

```

Mode-Pattern = Mode-Symbol [ "of" Loci ] .
Attribute-Pattern = Locus "is" [ Attribute-Loci ] Attribute-Symbol .
Attribute-Loci = Loci | "(" Loci ")" .
Predicate-Pattern = [ Loci ] Predicate-Symbol [ Loci ] .
Functor-Pattern = [ Functor-Loci ] Functor-Symbol [ Functor-Loci ]
  | Left-Functor-Bracket Loci Right-Functor-Bracket .
Functor-Loci = Locus | "(" Loci ")" .

```

1113. Base class for patterns.

```

⟨Pattern objects (wsmarticle.pas) 1113⟩ ≡
  PatternPtr = ↑PatternObj;
  PatternObj = object (mObject)
    nPatternPos: Position;
    nPatternSort: ItemKind;
    constructor Init(const aPos: Position; aSort: ItemKind);
  end ;

```

See also sections 1115, 1117, 1119, and 1121.

This code is used in section 1110.

1114. ⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor PatternObj.Init(const aPos: Position; aSort: ItemKind);
begin nPatternPos ← aPos; nPatternSort ← aSort;
end;

1115. Mode patterns. The syntax for “mode patterns” looks like:

```

Mode-Pattern = Mode-Symbol [ "of" Loci ] .
⟨Pattern objects (wsmarticle.pas) 1113⟩ +≡
  ModePatternPtr = ↑ModePatternObj;
  ModePatternObj = object (PatternObj)
    nModeSymbol: Integer;
    nArgs: PList;
    constructor Init(const aPos: Position; aSymb: integer; aArgs: PList);
    destructor Done; virtual;
  end ;

```

1116. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor ModePatternObj.Init(const aPos: Position; aSymb: integer; aArgs: PList);
  begin inherited Init(aPos, itDefMode); nModeSymbol ← aSymb; nArgs ← aArgs;
end;
destructor ModePatternObj.Done;
  begin dispose(nArgs, Done);
end;

```

1117. Attribute patterns. Attributes can have loci prefixing the attribute symbol, but *not* suffixing the attribute symbol.

```
Attribute-Pattern = Locus "is" [ Attribute-Loci ] Attribute-Symbol .
Attribute-Loci = Loci | "(" Loci ")" .
⟨ Pattern objects (wsmarticle.pas) 1113 ⟩ +≡
  AttributePatternPtr = ↑AttributePatternObj;
  AttributePatternObj = object (PatternObj)
    nAttrSymbol: Integer;
    nArg: LocusPtr;
    nArgs: PList;
    constructor Init(const aPos: Position; aArg: LocusPtr; aSymb: integer; aArgs: PList);
    destructor Done; virtual;
  end ;
```

1118. Constructor.

```
⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor AttributePatternObj.Init(const aPos: Position; aArg: LocusPtr; aSymb: integer; aArgs:
  PList);
  begin inherited Init(aPos, itDefAttr); nAttrSymbol ← aSymb; nArg ← aArg; nArgs ← aArgs;
  end;
destructor AttributePatternObj.Done;
  begin dispose(nArg, Done); dispose(nArgs, Done);
  end;
```

1119. Predicate patterns. Predicates can have loci on either side of the predicate symbol, without requiring parentheses (unlike functors).

```
Predicate-Pattern = [ Loci ] Predicate-Symbol [ Loci ] .
⟨ Pattern objects (wsmarticle.pas) 1113 ⟩ +≡
  PredicatePatternPtr = ↑PredicatePatternObj;
  PredicatePatternObj = object (PatternObj)
    nPredSymbol: Integer;
    nLeftArgs, nRightArgs: PList;
    constructor Init(const aPos: Position; aLArgs: PList; aSymb: integer; aRArgs: PList);
    destructor Done; virtual;
  end ;
```

1120. Constructor.

```
⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor PredicatePatternObj.Init(const aPos: Position;
  aLArgs: PList; aSymb: integer; aRArgs: PList);
  begin inherited Init(aPos, itDefPred); nPredSymbol ← aSymb; nLeftArgs ← aLArgs;
  nRightArgs ← aRArgs;
  end;
destructor PredicatePatternObj.Done;
  begin dispose(nLeftArgs, Done); dispose(nRightArgs, Done);
  end;
```

1121. Functor pattern. Functors can have loci on either side. If more than one locus is used on one side, then it must be placed in parentheses and comma-separated. The syntax:

Functor-Pattern = [Functor-Loci] Functor-Symbol [Functor-Loci]
 | Left-Functor-Bracket Loci Right-Functor-Bracket .

Functor-Loci = Locus | "(" Loci ")" .

⟨Pattern objects (wsmarticle.pas) 1113⟩ +=

```

  FunctorSort = (InfixFunctor, CircumfixFunctor);
  FunctorPatternPtr = ↑FunctorPatternObj;
  FunctorPatternObj = object (PatternObj)
    nFunctKind: FunctorSort;
    constructor Init(const aPos: Position; aKind: FunctorSort);
  end ;
  CircumfixFunctorPatternPtr = ↑CircumfixFunctorPatternObj;
  CircumfixFunctorPatternObj = object (FunctorPatternObj)
    nLeftBracketSymb, nRightBracketSymb: integer;
    nArgs: PList;
    constructor Init(const aPos: Position; aLBSymb, aRBSymb: integer; aArgs: PList);
    destructor Done; virtual;
  end ;
  InfixFunctorPatternPtr = ↑InfixFunctorPatternObj;
  InfixFunctorPatternObj = object (FunctorPatternObj)
    nOperSymb: integer;
    nLeftArgs, nRightArgs: PList;
    constructor Init(const aPos: Position; aLArgs: PList; aSymb: integer; aRArgs: PList);
    destructor Done; virtual;
  end ;

```

1122. Constructor.

⟨Implementation for wsmarticle.pas 1034⟩ +=

```

constructor FunctorPatternObj.Init(const aPos: Position; aKind: FunctorSort);
  begin inherited Init(aPos, itDefFunc); nFunctKind ← aKind;
  end;
constructor CircumfixFunctorPatternObj.Init(const aPos: Position; aLBSymb, aRBSymb: integer;
  aArgs: PList);
  begin inherited Init(aPos, CircumfixFunctor); nLeftBracketSymb ← aLBSymb;
  nRightBracketSymb ← aRBSymb; nArgs ← aArgs;
  end;
destructor CircumfixFunctorPatternObj.Done;
  begin dispose(nArgs, Done);
  end;
constructor InfixFunctorPatternObj.Init(const aPos: Position; aLArgs: PList; aSymb: integer; aRArgs:
  PList);
  begin inherited Init(aPos, InfixFunctor); nOperSymb ← aSymb; nLeftArgs ← aLArgs;
  nRightArgs ← aRArgs;
  end;
destructor InfixFunctorPatternObj.Done;
  begin dispose(nLeftArgs, Done); dispose(nRightArgs, Done);
  end;

```

Section 21.8. DEFINITIONS

1123. In Mizar, we can redefine an existing definition (either changing the type of a term or “the right hand side” of a definition) *or* we can introduce a new definition. There are 5 different things we can introduce: structures, modes [types], functors [terms], predicates, and attributes. Rather than bombard the reader with a long chunk of grammar, let us divide it up into easy-to-digest pieces. The basic block structure of a definition is the same for all these situations, its grammar looks like:

```

Definitional-Item = Definitional-Block ";" .
Definitional-Block = "definition" { Definition-Item | Definition | Redefinition } "end" .
Definition-Item = Loci-Declaration | Permissive-Assumption | Auxiliary-Item .
Loci-Declaration = "let" Qualified-Variables [ "such" Conditions ] ";" .
Permissive-Assumption = Assumption .
Definition = Structure-Definition
| Mode-Definition
| Functor-Definition
| Predicate-Definition
| Attribute-Definition .

```

1124. Redefinitions. Redefinitions allow us to alter the type or meaning of a definition. This isn't willy-nilly, the user still needs to prove the redefined version is logically equivalent to the initial definition.

```

Redefinition =
  "redefine" ( Mode-Definition | Functor-Definition | Predicate-Definition | Attribute-Definition ) .

```

1125. Structure definitions. Structures intuitively correspond to new “gadgets” (sets equipped with extra structure), which is often presented in Mathematics as “just another tuple”. Mizar allows structures to inherit other structures, so a topological group extends a topological space structure *and* a magma structure (since a group in Mizar is a magma with some extra properties).

```

Structure-Definition =
  "struct" [ "(" Ancestors ")" ] Structure-Symbol [ "over" Loci ] "(#" Fields "#)" ";" .
Ancestors = Structure-Type-Expression { "," Structure-Type-Expression } .
Structure-Symbol = Symbol .
Loci = Locus { "," Locus } .
Fields = Field-Segment { "," Field-Segment } .
Locus = Variable-Identifier .
Variable-Identifier = Identifier .
Field-Segment = Selector-Symbol { "," Selector-Symbol } Specification .
Selector-Symbol = Symbol .
Specification = "->" Type-Expression .

```

1126. Definiens. Recall the grammar for Definiens looks like:

```

Definiens = Simple-Definiens | Conditional-Definiens .
Simple-Definiens = [ ":" Label-Identifier ":" ] ( Sentence | Term-Expression ) .
Label-Identifier = Identifier .
Conditional-Definiens = [ ":" Label-Identifier ":" ] Partial-Definiens-List
  [ "otherwise" ( Sentence | Term-Expression ) ] .
Partial-Definiens-List = Partial-Definiens { "," Partial-Definiens } .
Partial-Definiens = ( Sentence | Term-Expression ) "if" Sentence .

```

We begin with a base class for definiens. This is extended by *SimpleDefiniens* and *ConditionalDefiniens* classes.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  HowToDefine = (dfEmpty, dfMeans, dfEquals);
  DefiniensSort = (SimpleDefiniens, ConditionalDefiniens);
  DefiniensPtr = ↑DefiniensObj;
  DefiniensObj = object (MObject)
    nDefSort: DefiniensSort;
    nDefPos: Position;
    nDefLabel: LabelPtr;
    constructor Init(const aPos: Position; aLab: LabelPtr; aKind: DefiniensSort);
    destructor Done; virtual;
  end ;

```

1127. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor DefiniensObj.Init(const aPos: Position; aLab: LabelPtr; aKind: DefiniensSort);
  begin nDefSort ← aKind; nDefPos ← aPos; nDefLabel ← aLab;
  end;
destructor DefiniensObj.Done;
  begin if nDefLabel ≠ nil then dispose(nDefLabel, Done);
  end;

```

1128. Definiens expression. These nodes in the abstract syntax tree describe “the right hand side” of a definition. A simple definiens is just a pointer to one definiens expression object, for example.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  DefExpressionPtr = ↑DefExpressionObj;
  DefExpressionObj = object (MObject)
    nExprKind: ExpKind;
    nExpr: PObject;
    constructor Init(aKind: ExpKind; aExpr: PObject);
    destructor Done; virtual;
  end ;

```

1129. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor DefExpressionObj.Init(aKind: ExpKind; aExpr: Pobject);
  begin nExprKind ← aKind; nExpr ← aExpr;
  end;
destructor DefExpressionObj.Done;
  begin dispose(nExpr, Done);
  end;

```

1130. Simple definiens. This is the “default” definiens, i.e., the definiens which are not “by cases”.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  SimpleDefiniensPtr = ↑SimpleDefiniensObj;
  SimpleDefiniensObj = object (DefiniensObj)
    nExpression: DefExpressionPtr;
    constructor Init(const aPos: Position; aLab: LabelPtr; aDef: DefExpressionPtr);
    destructor Done; virtual;
  end ;

```

1131. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor SimpleDefiniensObj.Init(const aPos: Position; aLab: LabelPtr; aDef: DefExpressionPtr);
  begin inherited Init(aPos, aLab, SimpleDefiniens); nExpression ← aDef;
  end;
destructor SimpleDefiniensObj.Done;
  begin dispose(nExpression, Done); inherited Done;
  end;

```

1132. Definition for particular case. We have “⟨sentence or term⟩ if ⟨guard condition⟩” represented by a couple of pointers: one to the “sentence or term” definiens, and the second to the “guard” condition.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  PartDefPtr = ↑PartDefObj;
  PartDefObj = object (MObject)
    nPartDefiniens: DefExpressionPtr;
    nGuard: FormulaPtr;
    constructor Init(aPartDef: DefExpressionPtr; aGuard: FormulaPtr);
    destructor Done; virtual;
  end ;

```

1133. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor PartDefObj.Init(aPartDef: DefExpressionPtr; aGuard: FormulaPtr);
  begin nGuard ← aGuard; nPartDefiniens ← aPartDef;
  end;
destructor PartDefObj.Done;
  begin dispose(nPartDefiniens, Done); dispose(nGuard, Done);
  end;

```

1134. Conditional definiens. A conditional definiens consists of a finite list of pointers to *PartDef* objects, and a pointer to the default “otherwise” definien.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  ConditionalDefiniensPtr = ↑ConditionalDefiniensObj;
  ConditionalDefiniensObj = object (DefiniensObj)
    nConditionalDefiniensList: PList;
    nOtherwise: DefExpressionPtr;
    constructor Init(const aPos: Position; aLab: LabelPtr; aPartialDefs: PList;
      aOtherwise: DefExpressionPtr);
    destructor Done; virtual;
  end ;

```

1135. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor ConditionalDefiniensObj.Init(const aPos: Position;
    aLab: LabelPtr; aPartialDefs: PList; aOtherwise: DefExpressionPtr);
    begin inherited Init(aPos, aLab, ConditionalDefiniens); nConditionalDefiniensList ← aPartialDefs;
    nOtherwise ← aOtherwise;
    end;
destructor ConditionalDefiniensObj.Done;
    begin if nOtherwise ≠ nil then dispose(nOtherwise, Done);
    dispose(nConditionalDefiniensList, Done); inherited Done;
    end;

```

1136. Mode definitions. Mizar was heavily inspired by ALGOL, and even borrows ALGOL's terminology for types ("modes"). These are "soft types", which are predicates in the ambient logic.

However, we need to establish the well-definedness of types (i.e., they are inhabited by at least one term), or else we end up in "free logic". For example, if `EmptyType` is a hypothetical empty type, then **for** `x` **being** `EmptyType` **holds** `P[x]` is always true, and **ex** `x` **being** `EmptyType` **st** `P[x]` is always false. The clever Mizar user can abuse this, and end up compromising the soundness of classical logic. To avert catastrophe, we require proving there exists at least one term of the newly defined type.

```

Mode-Definition = "mode" Mode-Pattern
    ( [ Specification ] [ "means" Definiens ] ";" Correctness-Conditions | "is" Type-Expression ";" )
    { Mode-Property } .
Mode-Pattern = Mode-Symbol [ "of" Loci ] .
Mode-Symbol = Symbol | "set" .
Mode-Synonym = "synonym" Mode-Pattern "for" Mode-Pattern ";" .
Mode-Property = "sethood" Justification ";" .

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
ModeDefinitionSort = (defExpandableMode, defStandardMode);
ModeDefinitionPtr = ↑ModeDefinitionObj;
ModeDefinitionObj = object (MObject)
    nDefKind: ModeDefinitionSort;
    nDefModePos: Position;
    nDefModePattern: ModePatternPtr;
    nRedefinition: boolean;
    constructor Init(const aPos: Position; aDefKind: ModeDefinitionSort; aRedef: boolean;
        aPattern: ModePatternPtr);
    destructor Done; virtual;
end ;

```

1137. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor ModeDefinitionObj.Init(const aPos: Position; aDefKind: ModeDefinitionSort;
    aRedef: boolean; aPattern: ModePatternPtr);
    begin nDefKind ← aDefKind; nDefModePos ← aPos; nRedefinition ← aRedef;
    nDefModePattern ← aPattern;
    end;
destructor ModeDefinitionObj.Done;
    begin dispose(nDefModePattern, Done);
    end;

```

1138. Expandable mode definitions. These are simple “abbreviations” of modes which are of the form “mode $\langle type\ name \rangle$ is $\langle adjective_1 \rangle \cdots \langle adjective_n \rangle \langle type \rangle$ ”, i.e., just a stack of adjectives atop a type.

```

< Publicly declared types in wsmarticle.pas 1032 > +≡
  ExpandableModeDefinitionPtr = ↑ExpandableModeDefinitionObj;
  ExpandableModeDefinitionObj = object (ModeDefinitionObj)
    nExpansion: TypePtr;
    constructor Init(const aPos: Position; aPattern: ModePatternPtr; aExp: TypePtr);
    destructor Done; virtual;
  end ;

```

1139. Constructor.

```

< Implementation for wsmarticle.pas 1034 > +≡
constructor ExpandableModeDefinitionObj.Init(const aPos: Position;
  aPattern: ModePatternPtr; aExp: TypePtr);
  begin inherited Init(aPos, defExpandableMode, false, aPattern); nExpansion ← aExp;
  end;
destructor ExpandableModeDefinitionObj.Done;
  begin dispose(nExpansion, Done); inherited Done;
  end;

```

1140. Standard mode definitions.

```

< Publicly declared types in wsmarticle.pas 1032 > +≡
  StandardModeDefinitionPtr = ↑StandardModeDefinitionObj;
  StandardModeDefinitionObj = object (ModeDefinitionObj)
    nSpecification: TypePtr;
    nDefiniens: DefiniensPtr;
    constructor Init(const aPos: Position; aRedef: boolean; aPattern: ModePatternPtr;
  aSpec: TypePtr; aDef: DefiniensPtr);
    destructor Done; virtual;
  end ;

```

1141. Constructor.

```

< Implementation for wsmarticle.pas 1034 > +≡
constructor StandardModeDefinitionObj.Init(const aPos: Position;
  aRedef: boolean; aPattern: ModePatternPtr; aSpec: TypePtr; aDef: DefiniensPtr);
  begin inherited Init(aPos, defStandardMode, aRedef, aPattern); nSpecification ← aSpec;
  nDefiniens ← aDef;
  end;
destructor StandardModeDefinitionObj.Done;
  begin dispose(nSpecification, Done); dispose(nDefiniens, Done); inherited Done;
  end;

```

1142. Attribute definitions. Attributes, like predicates, do not need to worry about correctness conditions. It's only when we want to use them like adjectives on a type that we need to worry, but that's a registration block concern.

```
Attribute-Definition = "attr" Attribute-Pattern "means" Definiens ";" Correctness-Conditions .
Attribute-Pattern = Locus "is" [ Attribute-Loci ] Attribute-Symbol .

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +=
  AttributeDefinitionPtr = ↑AttributeDefinitionObj;
  AttributeDefinitionObj = object (MObject)
    nDefAttrPos: Position;
    nDefAttrPattern: AttributePatternPtr;
    nRedefinition: boolean;
    nDefiniens: DefiniensPtr;
    constructor Init(const aPos: Position; aRedef: boolean; aPattern: AttributePatternPtr;
      aDef: DefiniensPtr);
    destructor Done; virtual;
  end ;
```

1143. Constructor.

```
⟨ Implementation for wsmarticle.pas 1034 ⟩ +=
constructor AttributeDefinitionObj.Init(const aPos: Position;
  aRedef: boolean; aPattern: AttributePatternPtr; aDef: DefiniensPtr);
begin nDefAttrPos ← aPos; nRedefinition ← aRedef; nDefAttrPattern ← aPattern;
  nDefiniens ← aDef;
end;

destructor AttributeDefinitionObj.Done;
begin dispose(nDefAttrPattern, Done); dispose(nDefiniens, Done);
end;
```

1144. Predicate definitions. Predicates are among the less demanding of the definitions: they are always well-defined, so we do not need to worry about correctness conditions.

```
Predicate-Definition = "pred" Predicate-Pattern [ "means" Definiens ] ";"
Correctness-Conditions { Predicate-Property } .
Predicate-Pattern = [ Loci ] Predicate-Symbol [ Loci ] .
Predicate-Property = ("symmetry" | "asymmetry" | "connectedness" | "reflexivity" | "irreflexivity")
  Justification ";" .
Predicate-Synonym = "synonym" Predicate-Pattern "for" Predicate-Pattern ";" .
Predicate-Antonym = "antonym" Predicate-Pattern "for" Predicate-Pattern ";" .
Predicate-Symbol = Symbol | "=" .

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +=
  PredicateDefinitionPtr = ↑PredicateDefinitionObj;
  PredicateDefinitionObj = object (MObject)
    nDefPredPos: Position;
    nDefPredPattern: PredicatePatternPtr;
    nRedefinition: boolean;
    nDefiniens: DefiniensPtr;
    constructor Init(const aPos: Position; aRedef: boolean; aPattern: PredicatePatternPtr;
      aDef: DefiniensPtr);
    destructor Done; virtual;
  end ;
```

1145. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor PredicateDefinitionObj.Init(const aPos: Position;
    aRedef: boolean; aPattern: PredicatePatternPtr; aDef: DefiniensPtr);
    begin nDefPredPos ← aPos; nRedefinition ← aRedef; nDefPredPattern ← aPattern;
    nDefiniens ← aDef;
    end;
destructor PredicateDefinitionObj.Done;
    begin dispose(nDefPredPattern, Done); dispose(nDefiniens, Done);
    end;

```

1146. Functor definitions. We can also define new terms. Well, they introduce “term constructors” (constructors for terms). Mizar calls these guys “functors”.

Functor definitions need to establish the well-definedness of the new term constructor. What this means depends on whether we define the new term using “means” or “equals”, i.e.,

- (1) “⟨new term⟩ means ⟨formula⟩” requires proving the existence and uniqueness of the new term;
- (2) “⟨new term⟩ equals ⟨term expression⟩” requires proving the new term has the given type.

Why do we need to prove well-definedness? Well, classical logic requires proving there exists a model for a theory, so our hands are tied. If we removed this restriction, then we’d end up with something called “free logic”, which is... weird.

```

Functor-Definition = "func" Functor-Pattern [ Specification ]
    [ ( "means" | "equals" ) Definiens ] ";"
    Correctness-Conditions { Functor-Property } .
Functor-Pattern = [ Functor-Loci ] Functor-Symbol [ Functor-Loci ]
    | Left-Functor-Bracket Loci Right-Functor-Bracket .
Functor-Property = ( "commutativity" | "idempotence" | "involutiveness" | "projectivity" )
    Justification ";" .
Functor-Synonym = "synonym" Functor-Pattern "for" Functor-Pattern ";" .
Functor-Loci = Locus | "(" Loci ")" .
Functor-Symbol = Symbol .
Left-Functor-Bracket = Symbol | "{" | "[" .
Right-Functor-Bracket = Symbol | "}" | "]" .
⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
    FunctorDefinitionPtr = ↑FunctorDefinitionObj;
    FunctorDefinitionObj = object (MObject)
        nDefFuncPos: Position;
        nDefFuncPattern: FunctorPatternPtr;
        nRedefinition: boolean;
        nSpecification: TypePtr;
        nDefiningWay: HowToDefine;
        nDefiniens: DefiniensPtr;
        constructor Init(const aPos: Position; aRedef: boolean; aPattern: FunctorPatternPtr;
            aSpec: TypePtr; aDefWay: HowToDefine; aDef: DefiniensPtr);
        destructor Done; virtual;
    end ;

```

1147. Constructor.

⟨Implementation for `wsmarticle.pas 1034`⟩ +≡
constructor *FunctorDefinitionObj.Init*(**const** *aPos*: *Position*; *aRedef*: *boolean*;
aPattern: *FunctorPatternPtr*; *aSpec*: *TypePtr*; *aDefWay*: *HowToDefine*; *aDef*: *DefiniensPtr*);
begin *nDefFuncPos* ← *aPos*; *nRedefinition* ← *aRedef*; *nDefFuncPattern* ← *aPattern*;
nSpecification ← *aSpec*; *nDefiningWay* ← *aDefWay*; *nDefiniens* ← *aDef*;
end;
destructor *FunctorDefinitionObj.Done*;
begin *dispose*(*nDefFuncPattern*, *Done*); *dispose*(*nDefiniens*, *Done*);
end;

1148. Notation block. We can recall the syntax for notation blocks.

Notation-Block = "notation" { Loci-Declaration | Notation-Declaration } "end" .

Notation-Declaration = Mode-Synonym
| Functor-Synonym
| Attribute-Synonym | Attribute-Antonym
| Predicate-Synonym | Predicate-Antonym .

Mode-Synonym = "synonym" Mode-Pattern "for" Mode-Pattern ";" .

Functor-Synonym = "synonym" Functor-Pattern "for" Functor-Pattern ";" .

Predicate-Synonym = "synonym" Predicate-Pattern "for" Predicate-Pattern ";" .

Predicate-Antonym = "antonym" Predicate-Pattern "for" Predicate-Pattern ";" .

Attribute-Synonym = "synonym" Attribute-Pattern "for" Attribute-Pattern ";" .

Attribute-Antonym = "antonym" Attribute-Pattern "for" Attribute-Pattern ";" .

The reader will observe all these notation items relate a new pattern which is either a synonym or antonym for an old pattern. That is to say, we only need two patterns to store as data in a notation item node in the abstract syntax tree.

⟨Publicly declared types in `wsmarticle.pas 1032`⟩ +≡
NotationDeclarationPtr = ↑*NotationDeclarationObj*;
NotationDeclarationObj = **object** (*mObject*)
nNotationPos: *Position*;
nNotationSort: *ItemKind*;
nOriginPattern, *nNewPattern*: *PatternPtr*;
constructor *Init*(**const** *aPos*: *Position*; *aNSort*: *ItemKind*; *aNewPatt*, *aOrigPatt*: *PatternPtr*);
destructor *Done*; *virtual*;
end ;

1149. Constructor.

⟨Implementation for `wsmarticle.pas 1034`⟩ +≡
constructor *NotationDeclarationObj.Init*(**const** *aPos*: *Position*; *aNSort*: *ItemKind*;
aNewPatt, *aOrigPatt*: *PatternPtr*);
begin *nNotationPos* ← *aPos*; *nNotationSort* ← *aNSort*; *nOriginPattern* ← *aOrigPatt*;
nNewPattern ← *aNewPatt*;
end;
destructor *NotationDeclarationObj.Done*;
begin *dispose*(*nOriginPattern*, *Done*); *dispose*(*nNewPattern*, *Done*);
end;

1150. Assumptions in a definition block. The syntax for assumptions in a definition block looks like:

```
Assumption = Single-Assumption | Collective-Assumption | Existential-Assumption .
Single-Assumption = "assume" Proposition ";" .
Collective-Assumption = "assume" Conditions ";" .
Existential-Assumption = "given" Qualified-Variables [ "such" Conditions ] ";" .
Conditions = "that" Proposition { "and" Proposition } .
Proposition = [ Label-Identifier ":" ] Sentence .
Sentence = Formula-Expression .
```

```
< Publicly declared types in wsmarticle.pas 1032 > +≡
  AssumptionKind = (SingleAssumption, CollectiveAssumption, ExistentialAssumption);
  AssumptionPtr = ↑AssumptionObj;
  AssumptionObj = object (MObject)
    nAssumptionPos: Position;
    nAssumptionSort: AssumptionKind;
    constructor Init(const aPos: Position; aSort: AssumptionKind);
  end ;
```

1151. Constructor.

```
< Implementation for wsmarticle.pas 1034 > +≡
constructor AssumptionObj.Init(const aPos: Position; aSort: AssumptionKind);
  begin nAssumptionPos ← aPos; nAssumptionSort ← aSort;
end ;
```

1152. Single assumption. When a definition has a single assumption, i.e., a single (usually labeled) formula.

```
< Publicly declared types in wsmarticle.pas 1032 > +≡
  SingleAssumptionPtr = ↑SingleAssumptionObj;
  SingleAssumptionObj = object (AssumptionObj)
    nProp: PropositionPtr;
    constructor Init(const aPos: Position; aProp: PropositionPtr);
    destructor Done; virtual;
  end ;
```

1153. Constructor.

```
< Implementation for wsmarticle.pas 1034 > +≡
constructor SingleAssumptionObj.Init(const aPos: Position; aProp: PropositionPtr);
  begin inherited Init(aPos, SingleAssumption); nProp ← aProp;
end ;
destructor SingleAssumptionObj.Done;
  begin dispose(nProp, Done);
end ;
```

1154. Collective assumption. This describes the case when the assumption is “assume C_1 and ... and C_n ”.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  CollectiveAssumptionPtr = ↑CollectiveAssumptionObj;
  CollectiveAssumptionObj = object (AssumptionObj)
    nConditions: PList;
    constructor Init(const aPos: Position; aProps: PList);
    destructor Done; virtual;
  end ;

```

1155. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor CollectiveAssumptionObj.Init(const aPos: Position; aProps: PList);
  begin inherited Init(aPos, CollectiveAssumption); nConditions ← aProps;
  end;
destructor CollectiveAssumptionObj.Done;
  begin dispose(nConditions, Done);
  end;

```

1156. Existential assumption. I must confess I am surprised to see an existential assumption node being a subclass of a collective assumption node.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  ExistentialAssumptionPtr = ↑ExistentialAssumptionObj;
  ExistentialAssumptionObj = object (CollectiveAssumptionObj)
    nQVars: PList;
    constructor Init(const aPos: Position; aQVars, aProps: PList);
    destructor Done; virtual;
  end ;

```

1157. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor ExistentialAssumptionObj.Init(const aPos: Position; aQVars, aProps: PList);
  begin AssumptionObj.Init(aPos, CollectiveAssumption); nConditions ← aProps; nQVars ← aQVars;
  end;
destructor ExistentialAssumptionObj.Done;
  begin dispose(nQVars, Done); inherited Done;
  end;

```

1158. Correctness conditions. The syntax for correctness conditions:

```
Correctness-Conditions = {Correctness-Condition} [ "correctness" Justification ";" ] .
Correctness-Condition =
  ( "existence" | "uniqueness" | "coherence" | "compatibility" | "consistency" | "reducibility" )
  Justification ";" .
```

We begin with an abstract base class for correctness conditions.

```
< Publicly declared types in wsmarticle.pas 1032 > +=
  CorrectnessPtr = ↑CorrectnessObj;
  CorrectnessObj = object (MObject)
    nCorrCondPos: Position;
    nJustification: JustificationPtr;
    constructor Init(const aPos: Position; aJustification: JustificationPtr);
    destructor Done; virtual;
  end ;
```

1159. Constructor.

```
< Implementation for wsmarticle.pas 1034 > +=
constructor CorrectnessObj.Init(const aPos: Position; aJustification: JustificationPtr);
  begin nCorrCondPos ← aPos; nJustification ← aJustification;
  end;
destructor CorrectnessObj.Done;
  begin dispose(nJustification, Done);
  end;
```

1160. Correctness condition. For the correctness condition associated with a definition or registration, we have this *CorrectnessCondition* object. When we need multiple correctness conditions, we extend it with a subclass.

```
< Publicly declared types in wsmarticle.pas 1032 > +=
  CorrectnessConditionPtr = ↑CorrectnessConditionObj;
  CorrectnessConditionObj = object (CorrectnessObj)
    nCorrCondSort: CorrectnessKind;
    constructor Init(const aPos: Position; aSort: CorrectnessKind; aJustification: JustificationPtr);
    destructor Done; virtual;
  end ;
```

1161. Constructor.

```
< Implementation for wsmarticle.pas 1034 > +=
constructor CorrectnessConditionObj.Init(const aPos: Position;
  aSort: CorrectnessKind; aJustification: JustificationPtr);
  begin inherited Init(aPos, aJustification); nCorrCondSort ← aSort;
  end;
destructor CorrectnessConditionObj.Done;
  begin inherited Done;
  end;
```

1162. Multiple correctness conditions. For, e.g., functors which require proving both “existence” and “uniqueness”, we have a *CorrectnessConditions* class. This extends the [singular] *CorrectnessCondition* class.

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
  CorrectnessConditionsSet = set of CorrectnessKind;
  CorrectnessConditionsPtr = ↑CorrectnessConditionsObj;
  CorrectnessConditionsObj = object (CorrectnessObj)
    nConditions: CorrectnessConditionsSet;
    constructor Init(const aPos: Position; const aConds: CorrectnessConditionsSet;
      aJustification: JustificationPtr);
    destructor Done; virtual;
  end ;

```

1163. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor CorrectnessConditionsObj.Init(const aPos: Position;
  const aConds: CorrectnessConditionsSet;
  aJustification: JustificationPtr);
begin inherited Init(aPos, aJustification); nConditions ← aConds;
end;
destructor CorrectnessConditionsObj.Done;
begin inherited Done;
end;

```

1164. Definition properties. The grammar for properties in a definition looks like:

Mode-Property = "sethood" Justification ";" .

Functor-Property = ("commutativity" | "idempotence" | "involutiveness" | "projectivity")
Justification ";" .

Predicate-Property = ("symmetry" | "asymmetry" | "connectedness" | "reflexivity" | "irreflexivity")
Justification ";" .

We see these are all, more or less, “the same”: we have a “kind” of property and a justification. We recall (§880) that we have already introduced the “kind” of properties. So the class describing a definition property node in the abstract syntax tree is:

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
  PropertyPtr = ↑PropertyObj;
  PropertyObj = object (MObject)
    nPropertyPos: Position;
    nPropertySort: PropertyKind;
    nJustification: JustificationPtr;
    constructor Init(const aPos: Position; aSort: PropertyKind; aJustification: JustificationPtr);
    destructor Done; virtual;
  end ;

```

1165. Constructor.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```

constructor PropertyObj.Init(const aPos: Position; aSort: PropertyKind;
    aJustification: JustificationPtr);
    begin nPropertyPos ← aPos; nPropertySort ← aSort; nJustification ← aJustification;
    end;
destructor PropertyObj.Done;
    begin inherited Done;
    end;

```

Section 21.9. REGISTRATIONS

1166. There are three “main” types of registrations, which are “cluster registrations” (because they all involve the “cluster” keyword):

- (1) Existential registrations are of the form “cluster $\langle attributes \rangle$ for $\langle type \rangle$ ” and establishes that a given attribute can act as an adjective for the type.
- (2) Conditional registrations are of the form “cluster $\langle attribute_1 \rangle \rightarrow \langle attribute_2 \rangle$ for $\langle type \rangle$ ” which tells Mizar that when $\langle attribute_1 \rangle$ is established for a term, then Mizar can automatically add $\langle attribute_2 \rangle$ for the term
- (3) Functorial registrations are of the form “cluster $\langle term \rangle \rightarrow \langle attribute \rangle$ [for $\langle type \rangle$]” which will automatically add an attribute to a term.

We also have three lesser registrations which are still important:

- (1) Sethood registrations, establishes a type can be used as a set in a Fraenkel term.
- (2) Reduction registration, which allows Mizar’s term rewriting module to use this rule when reasoning about things.
- (3) Identification registration, which allows Mizar to identify terms of different types.

```
Cluster-Registration = Existential-Registration
```

```
| Conditional-Registration
```

```
| Functorial-Registration .
```

```
Existential-Registration = "cluster" Adjective-Cluster "for" Type-Expression ";"
```

```
Correctness-Conditions .
```

```
Adjective-Cluster = { Adjective } .
```

```
Adjective = [ "non" ] [ Adjective-Arguments ] Attribute-Symbol .
```

```
Conditional-Registration = "cluster" Adjective-Cluster "->" Adjective-Cluster "for" Type-Expression ";"
```

```
Correctness-Conditions .
```

```
Functorial-Registration = "cluster" Term-Expression "->" Adjective-Cluster [ "for" Type-Expression ] ";"
```

```
Correctness-Conditions .
```

```
Identify-Registration = "identify" Functor-Pattern "with" Functor-Pattern
```

```
[ "when" Locus "=" Locus { ", " Locus "=" Locus } ] ";"
```

```
Correctness-Conditions .
```

```
Property-Registration = "sethood" "of" Type-Expression Justification ";" .
```

```
Reduction-Registration = "reduce" Term-Expression "to" Term-Expression ";"
```

```
Correctness-Conditions .
```

1167. Cluster registration. We have a base class for the three types of cluster registrations.

(Publicly declared types in `wsmarticle.pas` 1032) $\vdash \equiv$

```
ClusterRegistrationKind = (ExistentialRegistration, ConditionalRegistration, FunctorialRegistration);
```

```
ClusterPtr =  $\uparrow$ ClusterObj;
```

```
ClusterObj = object (MObject)
```

```
  nClusterPos: Position;
```

```
  nClusterKind: ClusterRegistrationKind;
```

```
  nConsequent: PList;
```

```
  nClusterType: TypePtr;
```

```
  constructor Init(const aPos: Position; aKind: ClusterRegistrationKind; aCons: PList;
```

```
    aTyp: TypePtr);
```

```
  destructor Done; virtual;
```

```
end ;
```

1168. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor ClusterObj.Init(const aPos: Position;
    aKind: ClusterRegistrationKind; aCons: PList; aTyp: TypePtr);
    begin nClusterPos ← aPos; nClusterKind ← aKind; nConsequent ← aCons; nClusterType ← aTyp;
    end;
destructor ClusterObj.Done;
    begin dispose(nConsequent, Done);
    end;

```

1169. Existential cluster. We register the fact there always exists a term of a given type satisfying an attribute (e.g., “empty” for “set” means there always exists an empty set; registering the existential cluster “non empty” for “set” means there always exists a nonempty set). This means the attribute may henceforth be used as an adjective on the type.

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
EClusterPtr = ↑EClusterObj;
EClusterObj = object (ClusterObj)
    constructor Init(const aPos: Position; aCons: PList; aTyp: TypePtr);
    destructor Done; virtual;
end ;

```

1170. Constructor. There are no additional fields to an existential cluster object, so it literally passes the parameters onto the superclass’s constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor EClusterObj.Init(const aPos: Position; aCons: PList; aTyp: TypePtr);
    begin ClusterObj.Init(aPos, ExistentialRegistration, aCons, aTyp);
    end;
destructor EClusterObj.Done;
    begin if nClusterType ≠ nil then dispose(nClusterType, Done);
    inherited Done;
    end;

```

1171. Conditional cluster. For example “empty sets” are always “finite sets”. This requires tracking the antecedent (“empty”), and the superclass tracks the consequents (“finite”).

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
CClusterPtr = ↑CClusterObj;
CClusterObj = object (ClusterObj)
    nAntecedent: PList;
    constructor Init(const aPos: Position; aAntec, aCons: PList; aTyp: TypePtr);
    destructor Done; virtual;
end ;

```

1172. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor CClusterObj.Init(const aPos: Position; aAntec, aCons: PList; aTyp: TypePtr);
    begin ClusterObj.Init(aPos, ConditionalRegistration, aCons, aTyp); nAntecedent ← aAntec;
    end;
destructor CClusterObj.Done;
    begin dispose(nAntecedent, Done); inherited Done;
    end;

```

1173. Functorial cluster. The generic form a functorial registrations associated to a term some cluster of adjectives. We need to track the term, but the superclass can manage the cluster of adjectives.

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
  FClusterPtr = ↑FClusterObj;
  FClusterObj = object (ClusterObj)
    nClusterTerm: TermPtr;
    constructor Init(const aPos: Position; aTrm: TermPtr; aCons: PList; aTyp: TypePtr);
    destructor Done; virtual;
  end ;

```

1174. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor FClusterObj.Init(const aPos: Position;
  aTrm: TermPtr; aCons: PList; aTyp: TypePtr);
  begin ClusterObj.Init(aPos, FunctorialRegistration, aCons, aTyp); nClusterTerm ← aTrm;
  end;
destructor FClusterObj.Done;
  begin if nClusterTerm ≠ nil then Dispose(nClusterTerm, Done);
  if nClusterType ≠ nil then dispose(nClusterType, Done);
  inherited Done;
  end;

```

1175. Loci equality. This is used in identification registrations.

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
  LociEqualityPtr = ↑LociEqualityObj;
  LociEqualityObj = object (mObject)
    nEqPos: Position;
    nLeftLocus, nRightLocus: LocusPtr;
    constructor Init(const aPos: Position; aLeftLocus, aRightLocus: LocusPtr);
    destructor Done; virtual;
  end ;

```

1176. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor LociEqualityObj.Init(const aPos: Position; aLeftLocus, aRightLocus: LocusPtr);
  begin nEqPos ← aPos; nLeftLocus ← aLeftLocus; nRightLocus ← aRightLocus;
  end;
destructor LociEqualityObj.Done;
  begin Dispose(nLeftLocus, Done); dispose(nRightLocus, Done);
  end;

```

1177. Identification registration. Term identification was first introduced in Artur Korniłowicz’s “How to define terms in Mizar effectively” (in A. Grabowski and A. Naumowicz (eds.), *Computer Reconstruction of the Body of Mathematics*, issue of *Studies in Logic, Grammar and Rhetoric* **18** no.31 (2009), pp. 67–77). See also §2.7 of Adam Grabowski, Artur Korniłowicz, and Adam Naumowicz’s “Mizar in a Nutshell” ([doi:10.6092/issn.1972-5787/1980](https://doi.org/10.6092/issn.1972-5787/1980)) for user-oriented details.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  IdentifyRegistrationPtr = ↑IdentifyRegistrationObj;
  IdentifyRegistrationObj = object (mObject)
    nIdentifyPos: Position;
    nOriginPattern, nNewPattern: PatternPtr;
    nEqLocList: PList;
    constructor Init(const aPos: Position; aNewPatt, aOrigPatt: PatternPtr; aEqList: PList);
    destructor Done; virtual;
  end ;

```

1178. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor IdentifyRegistrationObj.Init(const aPos: Position;
  aNewPatt, aOrigPatt: PatternPtr; aEqList: PList);
  begin nIdentifyPos ← aPos; nOriginPattern ← aOrigPatt; nNewPattern ← aNewPatt;
  nEqLocList ← aEqList;
  end;
destructor IdentifyRegistrationObj.Done;
  begin dispose(nOriginPattern, Done); dispose(nNewPattern, Done);
  if nEqLocList ≠ nil then dispose(nEqLocList, Done);
  end;

```

1179. Property registration. These were introduced in Mizar to facilitated registering “sethood” for types. Thus far, only the “sethood” property is handled in this registration.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  PropertyRegistrationPtr = ↑PropertyRegistrationObj;
  PropertyRegistrationObj = object (mObject)
    nPropertyPos: Position;
    nPropertySort: PropertyKind;
    constructor Init(const aPos: Position; aKind: PropertyKind);
    destructor Done; virtual;
  end ;

```

1180. Constructor.

```

⟨ Implementation for wsmarticle.pas 1034 ⟩ +≡
constructor PropertyRegistrationObj.Init(const aPos: Position; aKind: PropertyKind);
  begin nPropertyPos ← aPos; nPropertySort ← aKind;
  end;
destructor PropertyRegistrationObj.Done;
  begin end;

```

1181. Sethood registration. Artur Kornilowicz’s “Sethood Property in Mizar” (in *Joint Proc. FMM and LML Workshops*, 2019, ceur-ws.org/Vol-2634/FMM3.pdf) introduces this “sethood” property. It’s the first (and, so far, only) property registration in Mizar.

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
  SethoodRegistrationPtr = ↑SethoodRegistrationObj;
  SethoodRegistrationObj = object (PropertyRegistrationObj)
    nSethoodType: TypePtr;
    nJustification: JustificationPtr;
    constructor Init(const aPos: Position; aKind: PropertyKind; aType: TypePtr);
    destructor Done; virtual;
  end ;

```

1182. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor SethoodRegistrationObj.Init(const aPos: Position;
  aKind: PropertyKind; aType: TypePtr);
  begin inherited Init(aPos, aKind); nSethoodType ← aType; nJustification ← nil;
  end;
destructor SethoodRegistrationObj.Done;
  begin dispose(nSethoodType, Done); dispose(nJustification, Done); inherited Done;
  end;

```

1183. Reduce registration. These were introduced, I think, in Artur Kornilowicz’s “On rewriting rules in Mizar” (*J. Autom. Reason.* **50** no.2 (2013) 203–210, [doi:10.1007/s10817-012-9261-6](https://doi.org/10.1007/s10817-012-9261-6)). These extend the checker with new term rewriting rules.

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
  ReduceRegistrationPtr = ↑ReduceRegistrationObj;
  ReduceRegistrationObj = object (MObject)
    nReducePos: Position;
    nOriginTerm, nNewTerm: TermPtr;
    constructor Init(const aPos: Position; aOrigTerm, aNewTerm: TermPtr);
    destructor Done; virtual;
  end ;

```

1184. Constructor.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
constructor ReduceRegistrationObj.Init(const aPos: Position; aOrigTerm, aNewTerm: TermPtr);
  begin nReducePos ← aPos; nOriginTerm ← aOrigTerm; nNewTerm ← aNewTerm;
  end;
destructor ReduceRegistrationObj.Done;
  begin dispose(nOriginTerm, Done); dispose(nNewTerm, Done);
  end;

```

Section 21.10. HELPER FUNCTIONS

1185. Capitalization checks if the first character c is lowercase. If so, then set the leading character to be $c \leftarrow c - (\text{ord}(\text{'a'}) - \text{ord}(\text{'A'}))$. But it leaves the rest of the string untouched.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
function CapitalizeName(aName : string): string;
  begin result  $\leftarrow$  aName;
  if aName[1]  $\in$  ['a' .. 'z'] then dec(Result[1],  $\text{ord}(\text{'a'}) - \text{ord}(\text{'A'})$ )
  end;
```

1186. Uncapitalizing works in the opposite direction, setting the first letter c of a string to be $c \leftarrow c + (\text{ord}(\text{'a'}) - \text{ord}(\text{'A'}))$. Observe capitalizing and uncapitalizing are “nearly inverses” of each other: $\text{CapitalizeName}(\text{UncapitalizeName}(\text{CapitalizeName}(s))) = \text{CapitalizeName}(s)$, and similarly we find $\text{UncapitalizeName}(\text{CapitalizeName}(\text{UncapitalizeName}(s))) = \text{UncapitalizeName}(s)$.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
function UncapitalizeName(aName : string): string;
  begin result  $\leftarrow$  aName;
  if aName[1]  $\in$  ['A' .. 'Z'] then inc(Result[1],  $\text{ord}(\text{'a'}) - \text{ord}(\text{'A'})$ )
  end;
```

1187. We will be populating global variables tracking names of identifiers, modes, and other syntactic classes.

⟨Global variables publicly declared in `wsmarticle.pas` 1187⟩ ≡

```
var IdentifierName, AttributeName, StructureName, ModeName, PredicateName, FunctorName,
    SelectorName, LeftBracketName, RightBracketName, MMLIdentifierName: array of string;
```

This code is used in section 1030.

1188. We will want to initialize these global variables based on previous passes of the scanner.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
procedure InitScannerNames;
  var i, lCnt, lNr: integer; lDct: text; lInFile: XMLInStreamPtr; lKind, lDummy: AnsiChar;
  lString: string;
  begin ⟨Populate global variables with XML entities 1189⟩;
  ⟨Reset reserved keywords 1191⟩;
  { Identifiers }
  ⟨Initialize identifier names from .idx file 1192⟩;
  end;
```

1189. We need to initialize the length for each of these arrays. Even a crude approximation works, like the total number of lines in the `.dct` file. Then we transform each line of the `lDct` (dictionary file) into appropriate entries of the relevant array.

```

⟨Populate global variables with XML entities 1189⟩ ≡
  assign(lDct, MizFileName + ` .dct `); reset(lDct); lCnt ← 0;
  while ¬seekEof(lDct) do
    begin readln(lDct); inc(lCnt);
    end;
  setlength(AttributeName, lCnt); setlength(StructureName, lCnt); setlength(ModeName, lCnt);
  setlength(PredicateName, lCnt); setlength(FunctorName, lCnt); setlength(SelectorName, lCnt);
  setlength(LeftBracketName, lCnt); setlength(RightBracketName, lCnt);
  setlength(MMLIdentifierName, lCnt); reset(lDct);
  while ¬seekEof(lDct) do
    begin readln(lDct, lKind, lNr, lDummy, lString); ⟨Store XML version of vocabulary word 1190⟩;
    end;
  close(lDct)

```

This code is used in section 1188.

1190. We have read in from the “`.dct`” file one line. The first 148 lines of a “`.dct`” file consists of the reserved keywords for Mizar. A random example of the last few lines of such a file look like:

```

A36 VECTSP_4
A37 ORDINAL1
A38 CARD_FIL
A39 RANKNULL
A40 VECTSP_1
A41 VECTSP_6
A42 VECTSP13
A43 ALGSTR_0
A44 HALLMAR1
A45 MATROIDO

```

So we read the first leading letter of a line into `lKind`, then the number into `lNr`, the space is stuffed into `lDummy`, and the remainder of the line is placed in `lString`.

```

⟨Store XML version of vocabulary word 1190⟩ ≡
  case lKind of
    `A`: MMLIdentifierName[lNr] ← QuoteStrForXML(lString);
    `G`: StructureName[lNr] ← QuoteStrForXML(lString);
    `M`: ModeName[lNr] ← QuoteStrForXML(lString);
    `K`: LeftBracketName[lNr] ← QuoteStrForXML(lString);
    `L`: RightBracketName[lNr] ← QuoteStrForXML(lString);
    `O`: FunctorName[lNr] ← QuoteStrForXML(lString);
    `R`: PredicateName[lNr] ← QuoteStrForXML(lString);
    `U`: SelectorName[lNr] ← QuoteStrForXML(lString);
    `V`: AttributeName[lNr] ← QuoteStrForXML(lString);
  endcases

```

This code is used in section 1189.

1191. Preserve reserved keywords. We want to prevent the user from “overwriting” or “shadowing” the builtin primitive reserved words. This should probably be documented in the user-manual somewhere. The reserved words are: “**strict**”, “**set**”, “**=**”, and the brackets `[]`, braces `{}`, and parentheses `()`. Curiously, “**object**” is not considered a ‘primitive’ worth preserving.

```

⟨Reset reserved keywords 1191⟩ ≡
  AttributeName[StrictSym] ← `strict`; ModeName[SetSym] ← `set`;
  PredicateName[EqualitySym] ← `=`; LeftBracketName[SquareBracket] ← `[`;
  LeftBracketName[CurlyBracket] ← `{`; LeftBracketName[RoundedBracket] ← `(`;
  RightBracketName[SquareBracket] ← `]`; RightBracketName[CurlyBracket] ← `}`;
  RightBracketName[RoundedBracket] ← `)`

```

This code is used in section 1188.

1192. The `.idx` file provides numbers for the local labels and article names referenced in an article.

```

⟨Initialize identifier names from .idx file 1192⟩ ≡
  assign(lDct, MizFileName + `.idx`); reset(lDct); lCnt ← 0;
  while ¬seekEof(lDct) do
    begin readln(lDct); inc(lCnt);
    end;
  close(lDct);
  setlength(IdentifierName, lCnt); IdentifierName[0] ← ``;
  lInFile ← new(XMLInStreamPtr, OpenFile(MizFileName + `.idx`)); lInFile↑.NextElementState;
  lInFile↑.NextElementState;
  while (lInFile.nState = eStart) ∧ (lInFile.nElName = XMLElemName[elSymbol]) do
    begin lNr ← lInFile↑.GetIntAttr(`nr`); lString ← lInFile↑.GetAttr(`name`);
    IdentifierName[lNr] ← lString; lInFile↑.NextElementState; lInFile↑.NextElementState;
    end;
  dispose(lInFile, Done)

```

This code is used in section 1188.

1193. We will want to obtain the name for an article ID number, provided it is a legal number (i.e., less than the dictionary for article ID numbers). This function looks up its entry in the *IdentifierName* array.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
function IdentRepr(aIdNr : integer): string;
begin mizassert(2000, aIdNr ≤ length(IdentifierName));
  if aIdNr > 0 then IdentRepr ← IdentifierName[aIdNr]
  else IdentRepr ← ``;
end;

```

Section 21.11. WRITING WSM XML FILES

1194.

```

⟨ Publicly declared types in wsmarticle.pas 1032 ⟩ +≡
  OutWSMizFilePtr = ↑ OutWSMizFileObj;

    procedure Out_Justification(aInf : JustificationPtr; aBlock : wsBlockPtr); virtual;
  end ;

```

1195. Constructor. The constructor *OutWSMizFileObj.OpenFileWithXSL* is not used anywhere, nor is the associated “wsmiz.xml” file present anywhere.

Importantly, the *nMizarAppearance* field controls whether the XML generated includes the raw lexeme string as an attribute in the XML elements or not.

The constructor *OpenFileWithXSL* is never used. The XML stylesheet *wsmiz.xml* does not seem to be present in the Mizar distribution.

⟨Implementation for *wsmarticle.pas* 1034⟩ +≡

```

constructor OutWSMizFileObj.OpenFile(const aFileName: string);
  begin inherited OpenFile(aFileName); nMizarAppearance ← false;
  nDisplayInformationOnScreen ← false;
  end;
constructor OutWSMizFileObj.OpenFileWithXSL(const aFileName: string);
  begin inherited OpenFile(aFileName);
  OutString(‘<?xml-stylesheet_type="text/xml" href="file://’ + MizFiles + ‘wsmiz.xml"?>’ + #10);
  nMizarAppearance ← false;
  end;
destructor OutWSMizFileObj.Done;
  begin inherited Done;
  end;

```

1196. We can write the XML for a *wsTextProper* object (§1036). This writes out the start tag, the children, and the end-tag for the “text proper” and its contents. The RNG compact schema for this looks like:

```

TextProper = element Text-Propser {
  attribute idnr { xsd:integer },
  attribute col { xsd:integer },
  attribute line { xsd:integer },
  Item*
}

```

⟨Implementation for *wsmarticle.pas* 1034⟩ +≡

```

procedure OutWSMizFileObj.Out_TextProper(aWSTextProper : WSTextProperPtr);
  var i: integer;
  begin with aWSTextProper↑ do
    begin { Write the start-tag }
    Out_XElStart(BlockName[blMain]); Out_XAttr(XMLAttrName[atArticleId], nArticleId);
    Out_XAttr(XMLAttrName[atArticleExt], nArticleExt); Out_PosAsAttrs(nBlockPos); Out_XAttrEnd;
    for i ← 0 to nItems↑.Count − 1 do Out_Item(nItems.Items↑[i]); { ...then write the children }
    Out_XElEnd(BlockName[blMain]);
  end;
end;

```

1197. Writing a block out as XML works similarly: write the start-tag, then its children elements, then the end-tag.

```
Block = element Block {
  attribute kind { "Text-Propert" | "Now-Reasoning"
    | "Hereby-Reasoning" | "Definitional-Block"
    | "Notation-Block" | "Registration-Block" | "Case"
    | "Suppose" | "Scheme-Block" },
  attribute idnr { xsd:integer },
  attribute col { xsd:integer },
  attribute line { xsd:integer },
  Item*
}
```

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
procedure OutWSMizFileObj.Out_Block(aWSBlock : WSBlockPtr);
var i: integer;
begin with aWSBlock↑ do
  begin { write the start-tag }
    Out_XElStart(XMLElemName[elBlock]);
    Out_XAttr(XMLAttrName[atKind], BlockName[nBlockKind]); CurPos ← nBlockPos;
    Out_PosAsAttrs(nBlockPos); Out_XIntAttr(XMLAttrName[atPosLine], nBlockEndPos.Line);
    Out_XIntAttr(XMLAttrName[atPosCol], nBlockEndPos.Col); Out_XAttrEnd;
    for i ← 0 to nItems↑.Count − 1 do
      begin Out_Item(nItems↑.Items↑[i]); end; { Then write the children }
    Out_XElEnd(XMLElemName[elBlock]);
  end;
end;
```

1198. Writing a term list to XML amounts to just writing the terms as XML elements. They will be contained in a parent element, so there will be no ambiguity in their role.

```
Term-List = ( Term* )
```

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
procedure OutWSMizFileObj.Out_TermList(aTrmList : PList);
var i: integer;
begin for i ← 0 to aTrmList↑.Count − 1 do Out_Term(aTrmList↑.Items↑[i]);
end;
```

1199. The XML for an adjective boils down to two cases:

Case 1 (negated attribute). Write a `<NegatedAdjective>` tag around the XML produced from case 2 for the positive version of the attribute.

Case 2 (positive attribute). Write the adjective, and its children are the [term] arguments to the adjective (if any — if there are none, then an empty-element will be produced).

```

PositiveAdjective = element Adjective {
  attribute nr { xsd:integer },
  attribute name { text },
  attribute spelling { text }?,
  attribute col { xsd:integer },
  attribute line { xsd:integer }
  Term*
}
Adjective = PositiveAdjective | element NegatedAdjective {
  attribute col { xsd:integer },
  attribute line { xsd:integer },
  PositiveAdjective
}
<Implementation for wsmarticle.pas 1034> +=
procedure OutWSMizFileObj.Out_Adjective(aAttr : AdjectiveExpressionPtr);
begin case aAttr↑.nAdjectiveSort of
  wsAdjective: begin Out_XElStart(XMLElemName[elAdjective]);
    with AdjectivePtr(aAttr)↑ do
      begin Out_XIntAttr(XMLAttrName[atNr], nAdjectiveSymbol);
        if nMizarAppearance then
          Out_XAttr(XMLAttrName[atSpelling], AttributeName[nAdjectiveSymbol]);
          Out_PosAsAttrs(nAdjectivePos);
        if nArgs↑.Count = 0 then Out_XElEnd0
        else begin Out_XAttrEnd; Out_TermList(nArgs); Out_XElEnd(XMLElemName[elAdjective]);
          end;
        end;
      end;
    end;
  wsNegatedAdjective: begin Out_XElStart(XMLElemName[elNegatedAdjective]);
    with NegatedAdjectivePtr(aAttr)↑ do
      begin Out_PosAsAttrs(nAdjectivePos); Out_XAttrEnd; Out_Adjective(nArg);
        end;
      Out_XElEnd(XMLElemName[elNegatedAdjective]);
      end;
    endcases;
  end;

```

1200. Writing an adjective list to XML amounts to stuffing all the adjectives into an element. If there are no adjectives, it is the empty-element.

```

Adjective-Cluster = element Adjective-Cluster {
  attribute count { xsd:integer },
  Adjective*
}

⟨Implementation for wsmarticle.pas 1034⟩ +≡
procedure OutWSMizFileObj.Out_AdjectiveList(aCluster : PList);
  var i: integer;
  begin Out_XElStart(XMLElemName[elAdjectiveCluster]);
  if aCluster↑.Count = 0 then
    begin Out_XElEnd0; exit;
    end;
  Out_XAttrEnd;
  with aCluster↑ do
    for i ← 0 to Count − 1 do Out_Adjective(Items↑[i]);
  Out_XElEnd(XMLElemName[elAdjectiveCluster]);
  end;

```

Subsection 21.11.1. Emitting XML for types

1201. Writing the XML for a Mizar type.

```

StandardType = element Standard-Type {
  attribute nr { xsd:integer },
  attribute spelling { text }?,
  attribute col { xsd:integer },
  attribute line { xsd:integer },
  Term*
}
StructureType = element Structure-Type {
  attribute nr { xsd:integer },
  attribute spelling { text }?,
  attribute col { xsd:integer },
  attribute line { xsd:integer },
  Term*
}
ClusteredType = element Clustered-Type {
  attribute col { xsd:integer },
  attribute line { xsd:integer },
  Adjective-Cluster,
  Type,
}
Type = StandardType | StructureType | ClusteredType

define print_arguments(#) ≡
  if nArgs↑.Count = 0 then Out_XElEnd0
  else begin Out_XAttrEnd; Out_TermList(nArgs); Out_XElEnd(TypeName[#]);
  end
end

⟨Implementation for wsmarticle.pas 1034⟩ +≡
procedure Out_WSMizFileObj.Out_Type(aTyp : TypePtr);
begin with aTyp↑ do
  case aTyp↑.nTypeSort of
    wsStandardType: with StandardTypePtr(aTyp)↑ do
      begin Out_XElStart(TypeName[wsStandardType]);
      Out_XIntAttr(XMLAttrName[atNr], nModeSymbol);
      if nMizarAppearance then Out_XAttr(XMLAttrName[atSpelling], ModeName[nModeSymbol]);
      Out_PosAsAttrs(nTypePos); print_arguments(wsStandardType);
      end;
    wsStructureType: with StructTypePtr(aTyp)↑ do
      begin Out_XElStart(TypeName[wsStructureType]);
      Out_XIntAttr(XMLAttrName[atNr], nStructSymbol);
      if nMizarAppearance then
        Out_XAttr(XMLAttrName[atSpelling], StructureName[nStructSymbol]);
      Out_PosAsAttrs(nTypePos); print_arguments(wsStructureType);
      end;
    wsClusteredType: with ClusteredTypePtr(aTyp)↑ do
      begin Out_XElStart(TypeName[wsClusteredType]); Out_PosAsAttrs(nTypePos); Out_XAttrEnd;
      Out_AdjectiveList(nAdjectiveCluster); Out_Type(nType);
      Out_XElEnd(TypeName[wsClusteredType]);
      end;
    wsErrorType: begin Out_XElWithPos(TypeName[wsErrorType], nTypePos);
      end;
  endcases;

```

end;

1202. Printing a variable as an XML element.

```
Variable = element Variable {
  attribute idnr { xsd:integer },
  attribute spelling { text }?,
  attribute col { xsd:integer },
  attribute line { xsd:integer }
}

⟨Implementation for wsmarticle.pas 1034⟩ +≡
procedure OutWSMizFileObj.Out_Variable(aVar : VariablePtr);
  begin with aVar↑ do
    begin Out_XElStart(XMLElemName[elVariable]); Out_XIntAttr(XMLAttrName[atIdNr], nIdent);
    if nMizarAppearance then Out_XAttr(XMLAttrName[atSpelling], IdentRepr(nIdent));
    Out_PosAsAttrs(nVarPos); Out_XElEnd0
    end;
  end;
```

1203. Variables introduced using “**reserve**” are just printed out like any other variable.

```
⟨Implementation for wsmarticle.pas 1034⟩ +≡
procedure OutWSMizFileObj.Out_ReservedVariable(aVar : VariablePtr);
  begin Out_Variable(aVar);
  end;
```

1204. Implicitly qualified variables (i.e., variables which are **reserved** with a type, then used in, e.g., a quantified formula) are just variables appearing as children of an “implicitly qualified” XML element.

```
VariableSegment |= element Implicitly-Qualified-Segment {
  attribute col { xsd:integer },
  attribute line { xsd:integer },
  Variable
}

⟨Implementation for wsmarticle.pas 1034⟩ +≡
procedure OutWSMizFileObj.Out_ImplicitlyQualifiedVariable(aSegm : ImplicitlyQualifiedSegmentPtr);
  begin Out_XElStart(SegmentKindName[ikImplQualifiedSegm]); Out_PosAsAttrs(aSegm↑.nSegmPos);
  Out_XAttrEnd; Out_Variable(aSegm↑.nIdentifier);
  Out_XElEnd(SegmentKindName[ikImplQualifiedSegm]);
  end;
```

1205. Qualified variable segments are either implicitly qualified (hence we use the previous function) or explicitly qualified (which look like “ $\langle \text{variable list} \rangle$ being $\langle \text{type} \rangle$ ”).

Explicitly qualified segments are an XML element with two children (a “variables” XML element, and a “type” XML element).

```
VariableSegment |= element Explicitly-Qualified-Segment {
  attribute col { xsd:integer },
  attribute line { xsd:integer },
  element Variables { Variable* },
  Type
}

⟨Implementation for wsmarticle.pas 1034⟩ +≡
procedure Out_WSMizFileObj.Out_VariableSegment(aSegm : QualifiedSegmentPtr);
  var i: integer;
  begin case aSegm↑.nSegmentSort of
    ikImplQualifiedSegm: Out_ImplicitlyQualifiedVariable(ImplicitlyQualifiedSegmentPtr(aSegm));
    ikExplQualifiedSegm: with ExplicitlyQualifiedSegmentPtr(aSegm)↑ do
      begin Out_XElStart(SegmentKindName[ikExplQualifiedSegm]); Out_PosAsAttrs(nSegmPos);
        Out_XAttrEnd; Out_XElStart0(XMLElemName[elVariables]);
        for i ← 0 to nIdentifiers↑.Count − 1 do Out_Variable(nIdentifiers↑.Items↑[i]);
        Out_XElEnd(XMLElemName[elVariables]); Out_Type(nType);
        Out_XElEnd(SegmentKindName[ikExplQualifiedSegm]);
      end;
    endcases;
  end;
```

1206. Private predicates have the XML schema

```
Private-Predicate-Formula = element Private-Predicate-Formula {
  attribute idnr { xsd:integer },
  attribute spelling { text }?,
  attribute col { xsd:integer },
  attribute line { xsd:integer },
  Term-List?
}

⟨Implementation for wsmarticle.pas 1034⟩ +≡
procedure Out_WSMizFileObj.Out_PrivatePredicativeFormula(aFrm : PrivatePredicativeFormulaPtr);
  begin with PrivatePredicativeFormulaPtr(aFrm)↑ do
    begin Out_XElStart(FormulaName[wsPrivatePredicateFormula]);
      Out_XIntAttr(XMLAttrName[atIdNr], nPredIdNr);
      if nMizarAppearance then Out_XAttr(XMLAttrName[atSpelling], IdentRepr(nPredIdNr));
      Out_PosAsAttrs(nFormulaPos);
      if nArgs↑.Count = 0 then Out_XElEnd0
    else begin Out_XAttrEnd; Out_TermList(nArgs);
      Out_XElEnd(FormulaName[wsPrivatePredicateFormula]);
    end;
    end;
  end;
```

Subsection 21.11.2. Emitting XML for formulas

1207. The XML schema for formulas looks something like:

```

Formula = NegatedFormula
| ConjunctiveFormula
| DisjunctiveFormula
| ConditionalFormula
| BiconditionalFormula
| FlexaryConjunctiveFormula
| FlexaryDisjunctiveFormula
| Predicative-Formula
| RightSideOf-Predicative-Formula
| Multi-Predicative-Formula
| Attributive-Formula
| Qualifying-Formula
| Universal-Quantifier-Formula
| Existential-Quantifier-Formula
| element Contradiction {
    attribute col { xsd:integer },
    attribute line { xsd:integer } }
| element Thesis {
    attribute col { xsd:integer },
    attribute line { xsd:integer } }
| element Formula-Error {
    attribute col { xsd:integer },
    attribute line { xsd:integer } }

```

(Implementation for `wsmarticle.pas` 1034) +=

```

procedure OutWSMizFileObj.Out_Formula(aFrm : FormulaPtr);
var i: integer;
begin case aFrm↑.nFormulaSort of
  wsNegatedFormula: ⟨Emit XML for negated formula (WSM) 1208⟩;
  wsConjunctiveFormula: ⟨Emit XML for conjunction (WSM) 1209⟩;
  wsDisjunctiveFormula: ⟨Emit XML for disjunction (WSM) 1210⟩;
  wsConditionalFormula: ⟨Emit XML for conditional formula (WSM) 1211⟩;

Section 21.12. READING WSM FILES (DEFERRED)

1277. Reading a WSM file amounts to reading an XML file, which means that the *XMLInStream* class (§688) is a natural parent class. Recall, the state of the *XMLInStream* contains the current start tag and a dictionary for the attributes and their values.

The code is a “mirror image” to writing XML files, and the XML schema guides the implementation.

```

⟨Publicly declared types in wsmarticle.pas 1032⟩ +≡
  InWSMizFilePtr = ↑InWSMizFileObj;
  InWSMizFileObj = object (XMLInStreamObj)
    nDisplayInformationOnScreen: boolean;

  end ;

```

1278. Constructor.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
constructor InWSMizFileObj.OpenFile(const aFileName: string);
  begin inherited OpenFile(aFileName); nDisplayInformationOnScreen ← false;
  end;
destructor InWSMizFileObj.Done;
  begin inherited Done;
  end;
```

1279. Getting the value for an attribute. Returns **nil** if there is no attribute with the given name. (Recall (§649), an *XMLAttr* is just a wrapper around a string *nValue*.)

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
function InWSMizFileObj.GetAttrValue(const aAttrName: string): string;
  var lObj: PObject;
  begin result ← ``; lObj ← nAttrVals.ObjectOf(aAttrName);
  if lObj ≠ nil then result ← XMLAttrPtr(lObj)↑.nValue;
  end;
```

1280. We can query for the *position* of the XML attribute.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
function InWSMizFileObj.GetAttrPos: Position;
  var lLine, lCol: XMLAttrPtr; lCode: integer;
  begin result.Line ← 1; result.Col ← 1;
  lLine ← XMLAttrPtr(nAttrVals.ObjectOf(XMLAttrName[atLine]));
  lCol ← XMLAttrPtr(nAttrVals.ObjectOf(XMLAttrName[atCol]));
  if (lLine ≠ nil) ∧ (lCol ≠ nil) then
    begin Val(lLine↑.nValue, result.Line, lCode); Val(lCol↑.nValue, result.Col, lCode);
    end;
  end;
```

1281. The state of the WSM parser may be described with a handful of lookup tables.

(Implementation for `wsmarticle.pas` 1034) +≡

      for e ← Low(XMLElemKind) to High(XMLElemKind) do
        ElemLookupTable.Insert(new(MStrPtr, Init(XMLElemName[e])));
      for a ← Low(XMLAttrKind) to High(XMLAttrKind) do
        AttrLookupTable.Insert(new(MStrPtr, Init(XMLAttrName[a])));
      for b ← Low(BlockKind) to High(BlockKind) do
        BlockLookupTable.Insert(new(MStrPtr, Init(BlockName[b])));
      for i ← Low(ItemKind) to High(ItemKind) do
        ItemLookupTable.Insert(new(MStrPtr, Init(ItemName[i])));
      for f ← Low(FormulaSort) to High(FormulaSort) do
        FormulaKindLookupTable.Insert(new(MStrPtr, Init(FormulaName[f])));
      for t ← Low(TermSort) to High(TermSort) do
        TermKindLookupTable.Insert(new(MStrPtr, Init(TermName[t])));
      for i ← itDefPred to itDefStruct do
        PatternKindLookupTable.Insert(new(MStrPtr, Init(DefPatternName[i])));
      for p ← Low(PropertyKind) to High(PropertyKind) do
        PropertyKindLookupTable.Insert(new(MStrPtr, Init(PropertyName[p])));
      for c ← Low(CorrectnessKind) to High(CorrectnessKind) do
        CorrectnessKindLookupTable.Insert(new(MStrPtr, Init(CorrectnessName[c])));
      end;
```

1282. We also need to free the memory consumed by the lookup tables.

(Implementation for `wsmarticle.pas` 1034) +≡

```
procedure DisposeWSLookupTables;
begin ElemLookupTable.Done; AttrLookupTable.Done; BlockLookupTable.Done;
      ItemLookupTable.Done; FormulaKindLookupTable.Done; TermKindLookupTable.Done;
      CorrectnessKindLookupTable.Done; PropertyKindLookupTable.Done;
      end;
```

1283. We can recall, from the XML dictionary module (§612), the different kinds of XML elements as specified by an enumerated constant. This converts the “nr” attribute to the human readable equivalents.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡
function *Str2XMLElemKind*(*aStr* : *string*): *XMLElemKind*;
 var *lNr*: *integer*;
 begin *lNr* ← *ElemLookupTable.IndexOfStr*(*aStr*);
 if *lNr* > −1 **then** *Str2XMLElemKind* ← *XMLElemKind*(*lNr*)
 else *Str2XMLElemKind* ← *elUnknown*;
 end;

1284. Like the previous function, this converts the “nr” attribute for a WSM Mizar attribute XML element into a human readable form.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡
function *Str2XMLAttrKind*(*aStr* : *string*): *XMLAttrKind*;
 var *lNr*: *integer*;
 begin *lNr* ← *AttrLookupTable.IndexOfStr*(*aStr*);
 if *lNr* > −1 **then** *Str2XMLAttrKind* ← *XMLAttrKind*(*lNr*)
 else *Str2XMLAttrKind* ← *atUnknown*;
 end;

1285. The “kinds” of different syntactic classes were introduced earlier in `wsmarticle.pas`, now we want to translate them into human readable form.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡
function *Str2BlockKind*(*aStr* : *string*): *BlockKind*;
 var *lNr*: *integer*;
 begin *lNr* ← *BlockLookupTable.IndexOfStr*(*aStr*);
 if *lNr* > −1 **then** *Str2BlockKind* ← *BlockKind*(*lNr*)
 else *Str2BlockKind* ← *blMain*;
 end;
function *Str2ItemKind*(*aStr* : *string*): *ItemKind*;
 var *lNr*: *integer*;
 begin *lNr* ← *ItemLookupTable.IndexOfStr*(*aStr*);
 if *lNr* > −1 **then** *Str2ItemKind* ← *ItemKind*(*lNr*)
 else *Str2ItemKind* ← *itIncorrItem*;
 end;
function *Str2PatterenKind*(*aStr* : *string*): *ItemKind*;
 var *lNr*: *integer*;
 begin *lNr* ← *PatternKindLookupTable.IndexOfStr*(*aStr*);
 if *lNr* > −1 **then** *Str2PatterenKind* ← *ItemKind*(*Ord*(*ItDefPred*) + *lNr*)
 else *Str2PatterenKind* ← *itIncorrItem*;
 end;
function *Str2FormulaKind*(*aStr* : *string*): *FormulaSort*;
 var *lNr*: *integer*;
 begin *lNr* ← *FormulaKindLookupTable.IndexOfStr*(*aStr*);
 if *lNr* > −1 **then** *Str2FormulaKind* ← *FormulaSort*(*lNr*)
 else *Str2FormulaKind* ← *wsErrorFormula*;
 end;

1286.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
function Str2TermKind(aStr : string): TermSort;
  var lNr: integer;
  begin lNr ← TermKindLookupTable.IndexOfStr(aStr);
  if lNr > -1 then Str2TermKind ← TermSort(lNr)
  else Str2TermKind ← wsErrorTerm;
  end;

function Str2PropertyKind(aStr : string): PropertyKind;
  var lNr: integer;
  begin lNr ← PropertyKindLookupTable.IndexOfStr(aStr);
  if lNr > -1 then Str2PropertyKind ← PropertyKind(lNr)
  end;

function Str2CorrectnessKind(aStr : string): CorrectnessKind;
  var lNr: integer;
  begin lNr ← CorrectnessKindLookupTable.IndexOfStr(aStr);
  if lNr > -1 then Str2CorrectnessKind ← CorrectnessKind(lNr)
  end;

```

Subsection 21.12.1. Parsing types

1287. Reading a “term list” just iteratively invokes *Read_Term* (§1301) until all the children have been read.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
function InWSMizFileObj.Read_TermList: PList;
  begin result ← new(PList, Init(0));
  while nState ≠ eEnd do result↑.Insert(Read_Term);
  end;

```

1288. An adjective is either “positive” (i.e., not negated) or “negative” (i.e., negated). We handle the first case in the “true” branch, and the second case in the “false” branch.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
function InWSMizFileObj.Read_Adjective: AdjectiveExpressionPtr;
  var lAttrNr: integer; lPos: Position; lNoneOcc: Boolean;
  begin if nElName = AdjectiveSortName[wsAdjective] then
    begin lPos ← GetAttrPos; lAttrNr ← GetIntAttr(XMLAttrName[atNr]); NextElementState;
    result ← new(AdjectivePtr, Init(lPos, lAttrNr, Read_TermList)); NextElementState;
    end
  else begin lPos ← GetAttrPos; NextElementState;
    result ← new(NegatedAdjectivePtr, Init(lPos, Read_Adjective)); NextElementState;
    end;
  end;

```

1289. Reading a list of adjectives just iterates over the children of an element.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
function InWSMizFileObj.Read_AdjectiveList: PList;
  begin result ← new(PList, Init(0)); NextElementState;
  while nState ≠ eEnd do result↑.Insert(Read_Adjective);
  NextElementState;
  end;

```

1290. There are three valid Mizar types: “standard” types, structure types, and expandable modes (i.e., a cluster of adjectives stacked atop a type). If the XML element fails to match these three, then we should produce an “incorrect type”.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
function InWSMizFileObj.Read_Type: TypePtr;
  var lList: Plist; lPos: Position; lModeSymbol: integer;
  begin if nElName = TypeName[wsStandardType] then
    begin lPos ← GetAttrPos; lModeSymbol ← GetIntAttr(XMLAttrName[atNr]); NextElementState;
    result ← new(StandardTypePtr, Init(lPos, lModeSymbol, Read_TermList)); NextElementState;
    end
  else if nElName = TypeName[wsStructureType] then
    begin lPos ← GetAttrPos; lModeSymbol ← GetIntAttr(XMLAttrName[atNr]); NextElementState;
    result ← new(StructTypePtr, Init(lPos, lModeSymbol, Read_TermList)); NextElementState;
    end
  else if nElName = TypeName[wsClusteredType] then
    begin lPos ← GetAttrPos; NextElementState; lList ← Read_AdjectiveList;
    result ← new(ClusteredTypePtr, Init(lPos, lList, Read_Type)); NextElementState;
    end
  else begin lPos ← GetAttrPos; NextElementState; result ← new(IncorrectTypePtr, Init(lPos));
    NextElementState;
  end
end;

```

Subsection 21.12.2. Parsing formulas

1291. Parsing a variable from XML just requires reading the attributes, since it is an empty-element.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
function InWSMizFileObj.Read_Variable: VariablePtr;
  var lPos: Position; lNr: integer;
  begin lPos ← GetAttrPos; lNr ← GetIntAttr(XMLAttrName[atIdNr]);
  NextElementState; { closes the variable's tag }
  result ← new(VariablePtr, Init(lPos, lNr));
  NextElementState; { starts the next tag }
end;

```

1292. Implicitly qualified variables are just wrappers around a variable.

```

⟨Implementation for wsmarticle.pas 1034⟩ +≡
function InWSMizFileObj.Read_ImplicitlyQualifiedSegment: ImplicitlyQualifiedSegmentPtr;
  var lPos: Position;
  begin lPos ← GetAttrPos; NextElementState;
  result ← new(ImplicitlyQualifiedSegmentPtr, Init(lPos, Read_Variable)); NextElementState;
end;

```

1293. Recall (§1205) that a “qualified segment” is either implicit (i.e., a wrapper around a single variable) or explicit (i.e., an element whose children are variables and a type).

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
function InWSMizFileObj.Read_VariableSegment: QualifiedSegmentPtr;
  var lPos: Position; lVar: VariablePtr; lList: PList;
  begin if nElName = SegmentKindName[ikImplQualifiedSegm] then
    begin result ← Read_ImplicitlyQualifiedSegment;
    end
  else if nElName = SegmentKindName[ikExplQualifiedSegm] then
    begin lPos ← GetAttrPos; NextElementState; lList ← new(PList, Init(0));
    NextElementState; { read the variables }
    while (nState = eStart) ∧ (nElName = XMLElemName[elVariable]) do
      lList↑.Insert(Read_Variable);
    NextElementState; { read the type }
    result ← new(ExplicitlyQualifiedSegmentPtr, Init(lPos, lList, Read_Type));
    NextElementState; { start the next tag }
    end
  end;
```

1294. Private predicates are empty elements, so we only need to read their attributes.

⟨Implementation for `wsmarticle.pas` 1034⟩ +≡

```
function InWSMizFileObj.Read_PrivatePredicativeFormula: PrivatePredicativeFormulaPtr;
  var lPos: Position; lNr: integer;
  begin lPos ← GetAttrPos; lNr ← GetIntAttr(XMLAttrName[atIdNr]); NextElementState;
  result ← new(PrivatePredicativeFormulaPtr, Init(lPos, lNr, Read_TermList)); NextElementState;
  end;
```

1295.

⟨Implementation for `wsmarticle.pas` 1034⟩ \equiv

```

function InWSMizFileObj.Read_Formula: FormulaPtr;

Detour: Pragas

1373. This chapter is a “detour” because it is out of order for the compiler, but it is a dependency for the next file (`parseradditions.pas`).

The `base/pragmas.pas` contains the global variables which are toggled by pragmas like “`::$P+`”. This will toggle the *ProofPragma*. In particular, when *ProofPragma* is true, then Mizar will double check the proofs. When *ProofPragma* is false, Mizar will skip the proofs.

```

⟨pragmas.pas 1373⟩ ≡
  ⟨GNU License 4⟩
unit pragmas;
  interface uses mobjects;
  var VerifyPragmaOn, VerifyPragmaOff: NatSet; VerifyPragmaIntervals: NatFunc;
      SchemePragmaOn, SchemePragmaOff: NatSet; SchemePragmaIntervals: NatFunc;
      ProofPragma: Boolean = true; { check the proofs? }

  procedure SetParserPragma(aPrg : string);
  procedure InsertPragma(aLine : integer; aPrg : string);
  procedure CompletePragmas(aLine : integer);
  procedure CanceledPragma ( const aPrg: string; var aKind: char; var aNbr: integer ) ;
implementation
  uses mizenv;

```

1374. Cancelling a definition or theorem is handled with the “`::$C`” pragma, which is administered only by the editors of the MML. For example “`::$CD`” will cancel a definition, “`CT`” will cancel a theorem, and “`CS`” cancels a scheme.

```

procedure CanceledPragma ( const aPrg: string; var aKind: char; var aNbr: integer ) ;
  var lStr: string; k, lCod: integer;
  begin aKind ← ‘_’;
  if (Copy(aPrg, 1, 2) = ‘$C’) then
    begin if (length(aPrg) ≥ 3) ∧ (aPrg[3] ∈ [‘D’, ‘S’, ‘T’]) then
      begin aKind ← aPrg[3]; lStr ← TrimString(Copy(aPrg, 4, length(aPrg) – 3)); aNbr ← 1;
      if length(lStr) > 0 then
        begin k ← 1;
        while (k ≤ length(lStr)) ∧ (lStr[k] ∈ [‘0’ .. ‘9’]) do inc(k);
        delete(lStr, k, length(lStr));
        if length(lStr) > 0 then Val(lStr, aNbr, lCod);
        end;
      end;
    end;
  end;

```

1375. The “`::$P+`” pragma instructs Mizar to start checking the proofs for correctness. The “`::$P-`” pragma instructs Mizar to skip checking proofs.

```

procedure SetParserPragma(aPrg : string);
  begin if copy(aPrg, 1, 3) = ‘$P+’ then
    begin ProofPragma  $\leftarrow$  true;
    end;
  if copy(aPrg, 1, 3) = ‘$P-’ then
    begin ProofPragma  $\leftarrow$  false;
    end;
  end;

```

1376. The “`::$S+`” pragma will tell Mizar to check the scheme references, whereas “`::$S-`” pragma tells Mizar to stop verifying scheme references.

The “`::$V+`” pragma enables the verifier, and the “`::$V-`” pragma disables the verifier (skipping all verification until it is re-enabled).

```

procedure InsertPragma(aLine : integer; aPrg : string);
  begin if copy(aPrg, 1, 3) = ‘$V+’ then
    begin VerifyPragmaOn.InsertElem(aLine); end;
  if copy(aPrg, 1, 3) = ‘$V-’ then
    begin VerifyPragmaOff.InsertElem(aLine); end;
  if copy(aPrg, 1, 3) = ‘$S+’ then
    begin SchemePragmaOn.InsertElem(aLine); end;
  if copy(aPrg, 1, 3) = ‘$S-’ then
    begin SchemePragmaOff.InsertElem(aLine); end;
  end;

```

1377. The *CompletePragmas* function will compute the intervals for which the pragmas are “active”, then check whether the given line number falls within the “active range”.

```

procedure CompletePragmas(aLine : integer);
  var i, j, a, b: integer; f: boolean;
  begin for i  $\leftarrow$  0 to VerifyPragmaOff.Count - 1 do
    begin f  $\leftarrow$  false; a  $\leftarrow$  VerifyPragmaOff.Items↑[i].X;
    for j  $\leftarrow$  0 to VerifyPragmaOn.Count - 1 do
      begin b  $\leftarrow$  VerifyPragmaOn.Items↑[j].X;
      if b  $\geq$  a then
        begin VerifyPragmaIntervals.Assign(a, b); f  $\leftarrow$  true; break; end;
      end;
    if  $\neg$ f then VerifyPragmaIntervals.Assign(a, aLine);
    end;
  for i  $\leftarrow$  0 to SchemePragmaOff.Count - 1 do
    begin f  $\leftarrow$  false; a  $\leftarrow$  SchemePragmaOff.Items↑[i].X;
    for j  $\leftarrow$  0 to SchemePragmaOn.Count - 1 do
      begin b  $\leftarrow$  SchemePragmaOn.Items↑[j].X;
      if b  $\geq$  a then
        begin SchemePragmaIntervals.Assign(a, b); f  $\leftarrow$  true; break; end;
      end;
    if  $\neg$ f then SchemePragmaIntervals.Assign(a, aLine);
    end;
  end;

```

1378. Now we initialize the global variables declared in this module.

```
begin VerifyPragmaOn.Init(10,10); VerifyPragmaOff.Init(10,10);  
      VerifyPragmaIntervals.InitNatFunc(10,10); SchemePragmaOn.Init(10,10);  
      SchemePragmaOff.Init(10,10); SchemePragmaIntervals.InitNatFunc(10,10);  
end.
```

File 23

Detour: Parser additions

1379. This chapter is a “detour” because we are “going out of [compiler] order” to discuss `parseradditions.pas`. Why? Well, because the file provides subclasses to those introduced in the abstract syntax unit, and are necessary for understanding the `parser.pas` unit.

One of the difficulties with this file is that there are 37 global variables declared here, and 46 module-wide variables, declared here. It’s hard to juggle that knowledge! These “global” variables really describe the state of the Parser, and do not seem to be used anywhere else.

For what it’s worth, this appears to be conventional among compilers in the 1990s to use global variables to control the state of the compiler. For example David Hanson and Christopher Fraser’s *A Retargetable C Compiler: Design and Implementation* (Addison-Wesley, 1995) has quite a few global variables. If we were starting from scratch, it would be more idiomatic to put the state in a *Parser* class instance, and we could then use this to unit test the parser. This would become conventional more than a decade after Hanson and Fraser’s book was published.

[[It would probably be wise to refactor the design to isolate these variables inside a `Parser` class, so they are not randomly distributed throughout this part of the program.]]

CONVENTIONS: The classes have methods prefixed by *Start*, *Process*, and *Finish*.

- The *Start* methods reset the state variables needed to parse the syntactic entity.
- The *Process* methods usually update the state variables, either allocating new objects or transferring the current contents of a state variable in a different state variable.
- The *Finish* methods construct a WSM abstract syntax tree for the parsed entity.

This code is used in section 1379.

1386. Constructor. The constructor for an extended block object invokes the parent class’s constructor (§854), initializes the instance variables, then its behaviour depends on whether we are constructing a “main” block or not.

```

⟨Extended block implementation 1386⟩ ≡
constructor extBlockObj.Init(fBlockKind : BlockKind);
  begin inherited Init(fBlockKind);
  ⟨Initialize default values for extBlock instance 1387⟩;
  if nBlockKind = blMain then ⟨Initialize main extBlock instance 1388⟩
  else ⟨Initialize “proper text” extBlock instance 1391⟩;
  end;

```

See also sections 1393, 1394, 1395, 1396, 1397, 1398, 1399, 1401, 1402, and 1403.

This code is used in section 1380.

1387. We have the default values suppose links are prohibited for the block, and there are no assumptions for the block. The last *wsItem* and *wsBlock* pointers are set to the global *gLastWSItem* and *gLastWSBlock* variables, respectively.

```

⟨Initialize default values for extBlock instance 1387⟩ ≡
  nLinked ← false; nLinkPos ← CurPos; nLinkAllowed ← false; nLinkProhibited ← true;
  nHasAssumptions ← false; gRedefinitions ← false;
  nLastWSItem ← gLastWSItem; nLastWSBlock ← gLastWSBlock;

```

This code is used in section 1386.

1388. The “main” block of text needs to load the formats file, and populate the *gFormatsColl* (§808) and the *gFormatsBase* (*ibid.*) global variables. The *parseraddition.pas* unit’s *gProofCnt* global variable is initialized to zero here.

```

⟨Initialize main extBlock instance 1388⟩ ≡
  begin nInDiffuse ← true; gProofCnt ← 0;
  FileExam(EnvFileName + ‘.frm’); gFormatsColl.LoadFormats(EnvFileName + ‘.frm’);
  gFormatsBase ← gFormatsColl.Count; setlength(Term, MaxSubTermNbr);
  end

```

This code is used in section 1386.

1389. ⟨Local variables for parser additions 1389⟩ ≡
Term: **array of** *TermPtr*; { (§913) }

See also sections 1408, 1412, 1418, 1421, 1424, 1425, 1428, 1432, 1438, 1440, 1442, 1449, 1451, 1454, 1458, 1464, 1472, 1478, 1482, 1489, 1497, 1511, 1562, and 1569.

This code is used in section 1379.

1390. ⟨Global variables introduced in *parseraddition.pas* 1382⟩ +≡
gProofCnt: *integer*;

1391. The “proper text” branch updates the *gLastWSBlock* global variable. For most of the kinds of blocks, we will have to toggle *nInDiffuse* to be true or false. For proof blocks, we will need to increment the “depth” counter tracking the proof block “nestedness”.

Only the “**case**” and “**suppose**” blocks, when determining if they are in “diffuse mode” or not, need to confer with the previous block. (Recall (§449), *StackedObj* classes has a *Previous* pointer.)

```

⟨ Initialize “proper text” extBlock instance 1391 ⟩ ≡
  begin gLastWSBlock ← gWsTextProper↑.NewBlock(nBlockKind, CurPos);
  mizassert(2341, gLastWSItem ≠ nil);
  if gLastWSItem↑.nItemKind ∈ [itDefinition, itRegularStatement, itSchemeBlock, itTheorem,
    itConclusion, itCaseBlock, itCorrCond, itCorrectness, itProperty, itPropertyRegistration] then
    wsItemPtr(gLastWSItem).nBlock ← gLastWSBlock;
  case nBlockKind of
    blDefinition: nInDiffuse ← false;
    blNotation: nInDiffuse ← false;
    blDiffuse: nInDiffuse ← true;
    blHereby: nInDiffuse ← true;
    blProof: begin nLastSentence ← gLastFormula; inc(gProofCnt); end;
    blCase: nInDiffuse ← extBlockPtr(Previous)↑.nInDiffuse;
    blSuppose: nInDiffuse ← extBlockPtr(Previous)↑.nInDiffuse;
    blRegistration: nInDiffuse ← false;
    blPublicScheme: nInDiffuse ← false;
  endcases;
end

```

This code is used in section 1386.

1392. Popping a block. When we “pop” a proof block, we need to track the formula that was just proven and store it in the global variable *gLastFormula*.

```

⟨ Global variables introduced in parseraddition.pas 1382 ⟩ +≡
gLastFormula: FormulaPtr;

```

1393. This actually implements the *Pop* method for blocks. When a block “closes” (i.e., the corresponding “**end**” statement has been encountered), we restore the global state’s *gLastWSItem* and *gLastWSBlock* pointers. When a proof block closes, we also restore the *gLastFormula* state.

Also note: the parent class’s method (§855) does nothing. This will be invoked in the *KillBlock* (§847).

```

⟨ Extended block implementation 1386 ⟩ +≡
procedure extBlockObj.Pop;
  begin gLastWSBlock↑.nBlockEndPos ← CurPos;
  case nBlockKind of
    blProof: begin gLastFormula ← nLastSentence; dec(gProofCnt); end;
  endcases;
  gLastWSItem ← nLastWSItem; gLastWSBlock ← nLastWSBlock; { restore the “last” pointers }
  inherited Pop;
end;

```

1394. Process “begin”. Mizar uses “begin” to start a new “section” at the top-level of an article. Recall the grammar for this bit of Mizar:

$$\begin{aligned}\langle \textit{Text-Propser} \rangle &::= \langle \textit{Section} \rangle \{ \langle \textit{Section} \rangle \} . \\ \langle \textit{Section} \rangle &::= \textbf{“begin”} \{ \langle \textit{Text-Item} \rangle \} .\end{aligned}$$

There are zero or more Text-Items in a section.

We should note that the main text is not organized as a linked list of “main” blocks. Instead, we have a single “main” block, and we just push an *itSection* item to its contents.

⟨Extended block implementation 1386⟩ +≡

```
procedure extBlockObj.ProcessBegin;
  begin nLinkAllowed ← false; nLinkProhibited ← true;
    gLastWSItem ← gWsTextPropser↑.NewItem(itSection, CurPos); nLastWSItem ← gLastWSItem;
    gLastWSBlock↑.nItems.Insert(gLastWSItem);
  end;
```

1395. This will add a pragma item to the current block. The Parser’s *ProcessPragmas* (§1815) invokes this method.

⟨Extended block implementation 1386⟩ +≡

```
procedure extBlockObj.ProcessPragma;
  begin nLinkAllowed ← false; nLinkProhibited ← true;
    { Create a new item }
    gLastWSItem ← gWsTextPropser↑.NewItem(itPragma, CurPos);
    gLastWSItem↑.nContent ← new(PragmaPtr, Init(CurWord.Spelling));
    { Insert the pragma, update last item in block }
    nLastWSItem ← gLastWSItem; gLastWSBlock↑.nItems.Insert(gLastWSItem);
  end;
```

1396. Starting the proper text will just update the *nBlockPos* field to whatever the current position is.

⟨Extended block implementation 1386⟩ +≡

```
procedure extBlockObj.StartProperText;
  begin gWSTextPropser↑.nBlockPos ← CurPos; end;
```

1397. Processing redefinitions sets the global variable *gRedefinitions* to the result of comparing the current word to the “redefine” keyword.

⟨Extended block implementation 1386⟩ +≡

```
procedure extBlockObj.ProcessRedefine;
  begin gRedefinitions ← CurWord.Kind = sy_Redefine; end;
```

1398. When a block statement is linked, but it should not, then we raise a 164 error. Otherwise, be sure to mark the block as linked (i.e., toggle *nLinked* to be true) and assign the *nLinkPos* to be the current position.

⟨Extended block implementation 1386⟩ +≡

```
procedure extBlockObj.ProcessLink;
  begin if CurWord.Kind ∈ [sy_Then, sy_Hence] then
    begin if nLinkProhibited then ErrImm(164);
      nLinked ← true; nLinkPos ← CurPos;
    end;
  end;
```

1399. Proof of a scheme. We should increment the proof depth global variable.

Recall that *ProofPragma* means “check the proof is valid?” In other words, when *ProofPragma* is false, we are skipping the proofs.

```

define thesis_formula  $\equiv$  new(ThesisFormulaPtr, Init(CurPos))
define thesis_prop  $\equiv$  new(PropositionPtr, Init(new(LabelPtr, Init(0, CurPos)), thesis_formula, CurPos))
define skipped_proof_justification  $\equiv$  new(JustificationPtr, Init(infSkippedProof, CurPos))
 $\langle$  Extended block implementation 1386  $\rangle + \equiv$ 
procedure extBlockObj.StartSchemeDemonstration;
begin inc(gProofCnt);
if  $\neg$ ProofPragma then  $\langle$  Mark schema proof as “skipped” 1400  $\rangle$ ;
end;

```

1400. When we skip the proof (due to pragmas being set), we just add the scheme as a compact statement whose justification is the “skipped proof justification”.

First, we create a new text item for the proper text global variable. Then we set its content to the compact statement with the “skipped” justification. Finally we add this item to the “last” (latest) *wsBlock* global variable.

```

 $\langle$  Mark schema proof as “skipped” 1400  $\rangle \equiv$ 
begin gLastWSItem  $\leftarrow$  gWsTextProper $\uparrow$ .NewItem(itConclusion, CurPos);
gLastWSItem $\uparrow$ .nContent  $\leftarrow$  new(CompactStatementPtr, Init(thesis_prop, skipped_proof_justification));
gLastWSBlock $\uparrow$ .nItems.Insert(gLastWSItem);
end

```

This code is used in section 1399.

1401. Finishing the proof for a scheme should decrement the global “proof depth” counter.

```

 $\langle$  Extended block implementation 1386  $\rangle + \equiv$ 
procedure extBlockObj.FinishSchemeDemonstration;
begin dec(gProofCnt); end;

```

1402. The factory method for *extBlock* creating an item will update the global *gItemPtr* variable (§850).

```

 $\langle$  Extended block implementation 1386  $\rangle + \equiv$ 
procedure extBlockObj.CreateItem(fItemKind : ItemKind);
begin gItemPtr  $\leftarrow$  new(extItemPtr, Init(fItemKind)); end;

```

1403. The factory method for *extBlock* creating a new block will update the *gBlockPtr* global variable (§850).

```

 $\langle$  Extended block implementation 1386  $\rangle + \equiv$ 
procedure extBlockObj.CreateBlock(fBlockKind : BlockKind);
begin gBlockPtr  $\leftarrow$  new(extBlockPtr, Init(fBlockKind)) end;

```

Section 23.2. EXTENDED ITEM CLASS

1404. The class diagram for extended items looks like:

Fig. 13. Class hierarchy for *extItemObj*. The base *MObject* class omitted from the hierarchy.

Recall (§1089) the regular statement kind is one of three possibilities: diffuse statement, compact statement, iterative equality.

The “Finish” methods updates the contents of the *extItem* class with a WSM abstract syntax tree for the statement.

Since this is a “stub”, I will just leave the placeholder chunk for the methods overridden by the extended Item class here (remove later).

⟨Methods overridden by extended Item class 866⟩ +≡

1405. ⟨Extended item class declaration 1405⟩ ≡
extItemPtr = ↑*extItemObj*;
extItemObj = **object** (*ItemObj*)
 nItemPos: *Position*;

 nLabelIdPos: *Position*;
 nLabel: *LabelPtr*;
 nPropPos: *Position*;
 nInference: *JustificationPtr*;
 nLinkable: *boolean*;
 nRegularStatementKind: *RegularStatementKind*;
 nItAllowed: *boolean*;
 constructor *Init*(*fKind* : *ItemKind*);
 procedure *Pop*; *virtual*;
 ⟨Methods overridden by extended Item class 866⟩
end ;

This code is used in section 1379.

Subsection 23.2.1. Constructor

1406. There are a number of comments in Polish which I haphazardly translated into English (“Przygotowanie definiensow:” translates as “Preparation of definiens:”; “Ew. zakaz przy obiektach ekspandowanych” translates as “Possible ban on expanded facilities”)

```

⟨ Extended item implementation 1406 ⟩ ≡
constructor extItemObj.Init(fKind : ItemKind);
  begin inherited Init(fKind);
  ⟨ Initialize the fields for newly allocated extItem object 1409 ⟩
  mizassert(2343, gLastWSBlock ≠ nil);
  if ¬(nItemKind ∈ [itReservation, itConstantDefinition, itExemplification, itGeneralization,
    itLocDeclaration]) then
    begin gLastWSItem ← gWsTextProper↑.NewItem(fKind, CurPos); nLastWSItem ← gLastWSItem;
    end;
  case nItemKind of
    ⟨ Initialize extended item by ItemKind 1410 ⟩
  endcases;
  if ¬(nItemKind ∈ [itReservation, itConstantDefinition, itExemplification, itGeneralization,
    itLocDeclaration]) then gLastWSBlock↑.nItems.Insert(gLastWSItem);
  end;

```

See also sections 1429, 1457, 1459, 1460, 1461, 1462, 1463, 1465, 1466, 1468, 1469, 1470, 1471, 1473, 1474, 1475, 1476, 1479, 1480, 1481, 1483, 1484, 1485, 1486, 1487, 1490, 1491, 1492, 1493, 1494, 1495, 1498, 1499, 1501, 1502, 1503, 1504, 1505, 1506, 1507, 1509, 1510, 1512, 1513, 1514, 1515, 1517, 1519, 1521, 1522, 1523, 1524, 1525, 1527, 1529, 1530, 1531, 1532, 1533, 1534, 1535, 1536, 1537, 1538, 1539, 1540, 1541, 1542, 1543, 1544, 1545, 1546, 1548, 1549, 1551, 1552, 1553, 1555, 1556, 1557, 1558, 1559, 1560, 1561, 1563, 1564, and 1565.

This code is used in section 1380.

1407. Initializing the fields. The *it_Allowed* global variable is toggled on and off when the Parser encounters “guards” in conditional definitions, whereas the *nItAllowed* fields reflects whether the sort of definition allows “it” in the definiens.

```

⟨ Global variables introduced in parseraddition.pas 1382 ⟩ +≡
dol_Allowed: Boolean;
it_Allowed: Boolean;
in_AggrPattern: Boolean;
gLastType: TypePtr;
gLastTerm: TermPtr;
gDefiningWay: HowToDefine;

```

1408. ⟨ Local variables for parser additions 1389 ⟩ +≡
gClusterSort: *ClusterRegistrationKind*;
gDefiniens: *DefiniensPtr*;
gPartialDefs: *PList*;
nDefiniensProhibited: *boolean*;
gSpecification: *TypePtr*;

1409. \langle Initialize the fields for newly allocated *extItem* object 1409 $\rangle \equiv$
 $nItemPos \leftarrow CurPos$; $gClusterSort \leftarrow ExistentialRegistration$; $nItAllowed \leftarrow false$; $it_Allowed \leftarrow false$;
 { global variable! }
 $in_AggrPattern \leftarrow false$; $dol_Allowed \leftarrow false$; $gSpecification \leftarrow nil$; $gLastType \leftarrow nil$;
 $gLastFormula \leftarrow nil$; $gLastTerm \leftarrow nil$;
 { Preparation of definiens: }
 $nDefiniensProhibited \leftarrow false$;
 { Possible ban on expanded facilities }
 $gDefiningWay \leftarrow dfEmpty$; $gDefiniens \leftarrow nil$; $gPartialDefs \leftarrow nil$; $nLinkable \leftarrow false$;

This code is used in section 1406.

1410. Kind-specific initialization. Each kind of item may need some specific initialization. We work through all the cases. The first two cases considered are generalization (“**let** $\langle Qualified Variables \rangle$ **be** [such $\langle Conditions \rangle$]”) and existential assumptions (“**given** $\langle Qualified Variables \rangle$ **such** $\langle Conditions \rangle$ ”). Existential assumptions need to toggle the “has assumptions” field to true for the global block pointer.

\langle Initialize extended item by *ItemKind* 1410 $\rangle \equiv$
 $itGeneralization$: ; { **let** statements }
 $itExistentialAssumption$: $ExtBlockPtr(gBlockPtr) \uparrow .nHasAssumptions \leftarrow true$;

See also sections 1413, 1415, 1417, 1419, 1422, and 1426.

This code is used in sections 1406 and 1424.

1411. Property initialization. Initializing a property statement *Item* should raise an error when the property does not appear in the correct block.

- Defining a predicate can support the following properties: symmetry, reflectivity, irreflexivity, transitivity, connectedness, asymmetry.
- Functors can support: associativity, commutativity, idempotence, involutiveness, and projectivity properties.
- Modes can support the sethood property.

In all other situations, an error should be flagged (the user is trying to assert an invalid property).

\langle Global variables introduced in *parseraddition.pas* 1382 $\rangle + \equiv$
 $gDefKind$: *ItemKind*;

1412. \langle Local variables for parser additions 1389 $\rangle + \equiv$
 $gExpandable$: *boolean*;
 $gPropertySort$: *PropertyKind*;

1413. \langle Initialize extended item by *ItemKind* 1410 $\rangle + \equiv$
 $itProperty$: **begin** $gPropertySort \leftarrow PropertyKind(CurWord.Nr)$;
case $PropertyKind(CurWord.Nr)$ **of**
 $sySymmetry, syReflexivity, syIrreflexivity, syTransitivity, syConnectedness, syAsymmetry$:
if $gDefKind \neq itDefPred$ **then**
begin $ErrImm(81)$; $gPropertySort \leftarrow sErrProperty$; **end**;
 $syAssociativity, syCommutativity, syIdempotence$: **if** $gDefKind \neq itDefFunc$ **then**
begin $ErrImm(82)$; $gPropertySort \leftarrow sErrProperty$; **end**;
 $syInvolutiveness, syProjectivity$: **if** $gDefKind \neq itDefFunc$ **then**
begin $ErrImm(83)$; $gPropertySort \leftarrow sErrProperty$; **end**;
 $sySethood$: **if** $(gDefKind \neq itDefMode) \vee gExpandable$ **then**
begin $ErrImm(86)$; $gPropertySort \leftarrow sErrProperty$; **end**;
endcases;
end;

1414. Reconsider initialization. We need to allocate a new (empty) list for the list of terms being reconsidered.

⟨Global variables introduced in `parseraddition.pas` 1382⟩ +≡
gReconsiderList: *PList*;

1415. ⟨Initialize extended item by *ItemKind* 1410⟩ +≡
itReconsider: *gReconsiderList* ← *new(PList, Init(0))*;

1416. We can have in Mizar “**suppose that** *<statement>*” (as well as “**case that...**”). But in those cases, the statement cannot be linked to the next statement (i.e., the next statement cannot begin with “**then...**”). Assumptions without “**that**” are always linkable.

Theorems, “regular statements”, and conclusions are always linkable.

1417. ⟨Initialize extended item by *ItemKind* 1410⟩ +≡
itRegularStatement: *nLinkable* ← *true*;
itConclusion: *nLinkable* ← *true*;
itPerCases: ;
itCaseHead: **if** *AheadWord.Kind* ≠ *sy_That* **then** *nLinkable* ← *true*;
itSupposeHead: **if** *AheadWord.Kind* ≠ *sy_That* **then** *nLinkable* ← *true*;
itTheorem: *nLinkable* ← *true*;
itAxiom: **if** ¬*AxiomsAllowed* **then** *ErrImm*(66);
itChoice: ;

1418. Initializing an assumption. Collective assumptions (“**assume that** *<formula>*”) are not linkable, but single assumptions (“**assume** *<Proposition>*”) are linkable. The statement will introduce a list of premises, which will be tracked in the *gPremises* local variable for the module.

⟨Local variables for parser additions 1389⟩ +≡
gPremises: *PList*;

1419. ⟨Initialize extended item by *ItemKind* 1410⟩ +≡
itAssumption: **begin if** *AheadWord.Kind* ≠ *sy_That* **then** *nLinkable* ← *true*;
 gPremises ← *nil*;
end;

1420. Definition items. Definition items need to be initialized with some nuance. Some definitions permit “**it**” to be used in the definiens, but others do not. Mizar toggles the global variables tracking this here. There is a common set of things toggled which we have isolated as the WEB macro *initialize_definition_item* common to initializing all definition items.

The correctness conditions are determined at this point, as well.

define *initialize_definition_item* ≡ *gCorrectnessConditions* ← []; *gDefPos* ← *CurPos*;
 gDefKind ← *nItemKind*

⟨Global variables introduced in `parseraddition.pas` 1382⟩ +≡
gCorrectnessConditions: *CorrectnessConditionsSet*;

1421. ⟨Local variables for parser additions 1389⟩ +≡
gDefPos: *Position*;
gStructPrefixes: *PList*;

1422. \langle Initialize extended item by *ItemKind* 1410 $\rangle + \equiv$
itLocDeclaration: ;
itDefMode: **begin** *nItAllowed* \leftarrow true; *gExpandable* \leftarrow false; *initialize_definition_item* **end**;
itDefAttr: **begin** *initialize_definition_item* **end**;
itAttrSynonym: **begin** *initialize_definition_item* **end**;
itAttrAntonym: **begin** *initialize_definition_item* **end**;
itModeNotation: **begin** *initialize_definition_item* **end**;
itDefFunc: **begin** *nItAllowed* \leftarrow true; *initialize_definition_item* **end**;
itFuncNotation: **begin** *initialize_definition_item*; **end**;
itDefPred, *itPredSynonym*, *itCluster*, *itIdentify*, *itReduction*:
begin *initialize_definition_item*; **end**;
itPropertyRegistration: **begin** *initialize_definition_item*; *gPropertySort* \leftarrow *PropertyKind*(*CurWord.Nr*);
end;
itDefStruct: **begin** *initialize_definition_item*; *gStructPrefixes* \leftarrow *new*(*PList*, *Init*(0)); **end**;
itCanceled: **begin** *ErrImm*(88); **end**;

1423. Correctness conditions. Registrations and definitions need correctness conditions to ensure the well-definedness of adjective clusters and terms. The correctness conditions needed for a definition (or registration) are inserted into the *gCorrectnessConditions* variable. When the correctness condition is found, we remove it from the *gCorrectnessConditions* set.

\langle Global variables introduced in *parseraddition.pas* 1382 $\rangle + \equiv$
gRedefinitions: boolean;

1424. \langle Local variables for parser additions 1389 $\rangle + \equiv$
gCorrCondSort: *CorrectnessKind*;
 \langle Initialize extended item by *ItemKind* 1410 $\rangle =$ *itCorrCond*:
if *CorrectnessKind*(*CurWord.Nr*) \in *gCorrectnessConditions* **then**

gNewPatternPos: Position;
gNewPattern: PatternPtr;
gSchemeIdNr: integer;
gSchemeIdPos: Position;
gSchemeConclusion: FormulaPtr;
gSchemePremises: PList;

```

Subsection 23.2.2. Popping

1429. Popping an item is invoked as part of *KillItem*, which occurs whenever (1) a semicolon is encountered, or (2) when starting a proof environment.

The contract for popping an item ensures the *nContent* field shall be populated for valid items.

NOTE: PASCAL has a set operation *include(set, element)* which adjoins an *element* to a *set*.

\langle Extended item implementation 1406 $\rangle + \equiv$

```

procedure extItemObj.Pop;
  var k: integer;
  begin gLastWSItem↑.nItemEndPos ← PrevPos;  $\langle$  Check for errors with definition items 1433  $\rangle$ 
   $\langle$  Update content of nLastWSItem based on type of item popped 1430  $\rangle$ ;
   $\langle$  Check the popped item's linkages are valid 1456  $\rangle$ ;
  if gDefiningWay ≠ dfEmpty then
    begin if gDefiniens↑.nDefSort = ConditionalDefiniens then
      include(gCorrectnessConditions, syConsistency);
    if gRedefinitions then include(gCorrectnessConditions, syCompatibility);
    end;
  inherited Pop; { (§864) }
  end;

```

1430. We will update the caller's *nLastWSItem*'s contents in most cases.

```

⟨ Update content of nLastWSItem based on type of item popped 1430 ⟩ ≡
  case nItemKind of
    itTheorem: nLastWSItem↑.nContent ← new(CompactStatementPtr, Init(new(PropositionPtr,
      Init(nLabel, gLastFormula, nPropPos)), nInference));
    ⟨ Pop a proof step 1434 ⟩
    itConclusion, itRegularStatement: ⟨ Pop a conclusion or regular statement 1441 ⟩
    itGeneralization, itLocDeclaration: ⟨ Pop a “let” statement 1443 ⟩
    ⟨ Pop a definition item 1444 ⟩
    itPredSynonym, itPredAntonym, itFuncNotation, itModeNotation, itAttrSynonym, itAttrAntonym:
      nLastWSItem↑.nContent ← new(NotationDeclarationPtr, Init(gNewPatternPos, nItemKind,
        gNewPattern, gPattern));
    ⟨ Pop a registration item 1452 ⟩
    itCorrCond: nLastWSItem↑.nContent ← new(CorrectnessConditionPtr, Init(nItemPos, gCorrCondSort,
      nInference));
    itCorrectness: nLastWSItem↑.nContent ← new(CorrectnessConditionsPtr, Init(nItemPos,
      gCorrectnessConditions, nInference));
    itProperty: nLastWSItem↑.nContent ← new(PropertyPtr, Init(nItemPos, gPropertySort, nInference));
    itSchemeHead: nLastWSItem↑.nContent ← new(SchemePtr, Init(gSchemeIdNr, gSchemeIdPos,
      gSchemeParams, gSchemePremises, gSchemeConclusion));
    ⟨ Pop skips remaining cases 1431 ⟩
  endcases

```

This code is used in section 1429.

1431. ⟨ Pop skips remaining cases 1431 ⟩ ≡

```

itPrivFuncDefinition, itPrivPredDefinition, itPragma, itDefinition, itSchemeBlock, itReservation,
  itExemplification, itCaseBlock: ;

```

This code is used in section 1430.

1432. Check for errors. We need to flag a 253 or 254 error when the user tries to introduce an axiom (which shouldn't occur much anymore, since axioms are not even documented anywhere).

```

⟨ Local variables for parser additions 1389 ⟩ +≡
  gMeansPos: Position;

```

1433. ⟨ Check for errors with definition items 1433 ⟩ ≡

```

case nItemKind of
  itDefPred, itDefFunc, itDefMode, itDefAttr: begin if gDefiningWay ≠ dfEmpty then
    begin if nDefiniensProhibited ∧ ¬AxiomsAllowed then
      begin Error(gMeansPos, 254); gDefiningWay ← dfEmpty; end;
    end
  else if ¬gRedefinitions ∧ ¬nDefiniensProhibited ∧ ¬AxiomsAllowed then SemErr(253);
  end;
endcases;

```

This code is used in section 1429.

1434. Pop a proof step. Popping a proof step should assign to the contents of the caller's *nLastWsItem* some kind of inference justification, usually in the form of a statement in the WSM syntax tree.

$\langle \text{Pop a proof step } 1434 \rangle \equiv$
itPerCases: *nLastWsItem*↑.*nContent* \leftarrow *nInference*;

See also sections 1435, 1437, and 1439.

This code is used in section 1430.

1435. Popping a reconsideration. We should assign a *TypeChangingStatement* to the content of the caller's last item, using the *nInference* field of the caller as the justification.

$\langle \text{Pop a proof step } 1434 \rangle + \equiv$
itReconsider: *nLastWsItem*↑.*nContent* \leftarrow *new*(*TypeChangingStatementPtr*, *Init*(*gReconsiderList*,
gLastType, *SimpleJustificationPtr*(*nInference*)));

1436. Popping existential elimination and introduction. We assign a *consider* (or *given*) WSM statement to the caller's previous *WSItem*'s contents when popping a choice (resp., existential assumption) item.

We should remind the reader of the grammar here:

$\langle \text{Qualified-Segment} \rangle ::= \langle \text{Variables} \rangle \langle \text{Qualification} \rangle$
 $\langle \text{Variables} \rangle ::= \langle \text{Variable} \rangle \{ \text{"}, \text{"} \langle \text{Variable} \rangle \}$
 $\langle \text{Qualification} \rangle ::= (\text{"being"} \mid \text{"be"}) \langle \text{Type-Expression} \rangle$

And, of course, a qualified-segment list is just a comma-separated list of qualified-segments.

$\langle \text{Global variables introduced in parseraddition.pas } 1382 \rangle + \equiv$
gQualifiedSegmentList: *PList*;

1437. $\langle \text{Pop a proof step } 1434 \rangle + \equiv$
itChoice: **begin** *nLastWsItem*↑.*nContent* \leftarrow *new*(*ChoiceStatementPtr*, *Init*(*gQualifiedSegmentList*,
gPremises, *SimpleJustificationPtr*(*nInference*))); *gPremises* \leftarrow **nil**;
end;
itExistentialAssumption: **begin** *nLastWsItem*↑.*nContent* \leftarrow *new*(*ExistentialAssumptionPtr*,
Init(*nItemPos*, *gQualifiedSegmentList*, *gPremises*)); *gPremises* \leftarrow **nil**;
end;

1438. Popping a stipulation. When we pop a *case*, *suppose*, or *assume* — some kind of “assumption”-like statement — we are assigning either a *CollectiveAssumption* object or a *SingleAssumption* object to the content of the *current WSItem global* variable.

$\langle \text{Local variables for parser additions } 1389 \rangle + \equiv$
gThatPos: *Position*;

1439. $\langle \text{Pop a proof step } 1434 \rangle + \equiv$
itSupposeHead, *itCaseHead*, *itAssumption*: **if** *gPremises* \neq **nil** **then**
begin *gLastWsItem*↑.*nContent* \leftarrow *new*(*CollectiveAssumptionPtr*, *Init*(*gThatPos*, *gPremises*));
gPremises \leftarrow **nil**;
end
else *gLastWsItem*↑.*nContent* \leftarrow *new*(*SingleAssumptionPtr*, *Init*(*nItemPos*, *new*(*PropositionPtr*,
Init(*nLabel*, *gLastFormula*, *nPropPos*))));

1440. Pop a conclusion or regular statement. We assign an appropriate WSM statement node to the previous item's contents.

\langle Local variables for parser additions 1389 $\rangle + \equiv$
gIterativeSteps: *PList*;
gIterativeLastFormula: *FormulaPtr*;
gInference: *JustificationPtr*;

1441. \langle Pop a conclusion or regular statement 1441 $\rangle \equiv$
case *nRegularStatementKind* **of**
stDiffuseStatement:
 nLastWSItem \uparrow .*nContent* \leftarrow *new*(*DiffuseStatementPtr*, *Init*(*nLabel*, *stDiffuseStatement*));
stCompactStatement: *nLastWSItem* \uparrow .*nContent* \leftarrow *new*(*CompactStatementPtr*, *Init*(*new*(*PropositionPtr*,
 Init(*nLabel*, *gLastFormula*, *nPropPos*)), *nInference*));
stIterativeEquality: *nLastWSItem* \uparrow .*nContent* \leftarrow *new*(*IterativeEqualityPtr*, *Init*(*new*(*PropositionPtr*,
 Init(*nLabel*, *gIterativeLastFormula*, *nPropPos*)), *gInference*, *gIterativeSteps*));
endcases;

This code is used in section 1430.

1442. Pop a ‘let’ statement. For generic let statements of the form

$$\text{let } \vec{x}_1 \text{ be } T_1, \dots, \vec{x}_n \text{ be } T_n$$

we transform it to *n* statements of the form “let \vec{x} be *T*”, then add these to the *gLastWSBlock*’s items. When we have

$$\text{let } \vec{x} \text{ be } T \text{ such that } \Phi$$

we need to add a *CollectiveAssumption* node to the **global** *gLastWSBlock*’s items.

\langle Local variables for parser additions 1389 $\rangle + \equiv$
gSuchPos: *Position*;

1443. \langle Pop a “let” statement 1443 $\rangle \equiv$
begin for *k* \leftarrow 0 **to** *gQualifiedSegmentList* \uparrow .*Count* $-$ 1 **do**
 begin *gLastWSItem* \leftarrow *gWsTextProper* \uparrow .*NewItem*(*nItemKind*,
 QualifiedSegmentPtr(*gQualifiedSegmentList* \uparrow .*Items* \uparrow [*k*]) \uparrow .*nSegmPos*);
 nLastWSItem \leftarrow *gLastWSItem*; *gLastWSItem* \uparrow .*nContent* \leftarrow *gQualifiedSegmentList* \uparrow .*Items* \uparrow [*k*];
 if *k* = *gQualifiedSegmentList* \uparrow .*Count* $-$ 1 **then** *gLastWSItem* \uparrow .*nItemEndPos* \leftarrow *PrevPos*
 else *gLastWSItem* \uparrow .*nItemEndPos* \leftarrow *QualifiedSegmentPtr*(*gQualifiedSegmentList* \uparrow .*Items* \uparrow [*k* +
 1]) \uparrow .*nSegmPos*;
 gQualifiedSegmentList \uparrow .*Items* \uparrow [*k*] \leftarrow **nil**; *gLastWSBlock* \uparrow .*nItems.Insert*(*gLastWSItem*);
 end;
 dispose(*gQualifiedSegmentList*, *Done*);
 if *gPremises* \neq **nil** **then**
 begin *gLastWSItem* \leftarrow *gWsTextProper* \uparrow .*NewItem*(*itAssumption*, *gSuchPos*);
 gLastWSItem \uparrow .*nContent* \leftarrow *new*(*CollectiveAssumptionPtr*, *Init*(*gThatPos*, *gPremises*));
 gPremises \leftarrow **nil**; *gLastWSItem* \uparrow .*nItemEndPos* \leftarrow *PrevPos*; *nLastWSItem* \leftarrow *gLastWSItem*;
 gLastWSBlock \uparrow .*nItems.Insert*(*gLastWSItem*);
 end;
 end;

This code is used in section 1430.

1444. Pop a mode definition. A mode is either expandable (an abbreviation) or nonexpandable. For expandable modes, we just add a new *ExpandableModeDefinition* WSM object to the caller's *nLastWSItem*'s contents.

On the other hand, non-expandable modes should add to the caller's *nLastWSItem*'s contents a new *StandardModeDefinition* object. If this is not a redefinition, then we must add the “**existence**” correctness condition to the global variable *gCorrectnessConditions*.

```

⟨Pop a definition item 1444⟩ ≡
itDefMode: begin if gExpandable then nLastWSItem↑.nContent ← new(ExpandableModeDefinitionPtr,
    Init(gPatternPos, ModePatternPtr(gPattern), gLastType))
else begin nLastWSItem↑.nContent ← new(StandardModeDefinitionPtr, Init(gPatternPos,
    gRedefinitions, ModePatternPtr(gPattern), gSpecification, gDefiniens));
    if ¬gRedefinitions then include(gCorrectnessConditions, syExistence);
    end;
end;

```

See also sections 1445, 1446, 1447, and 1450.

This code is used in section 1430.

1445. Pop a functor definition. When popping a functor definition, we just add a *FunctorDefinition* object to the caller's *nLastWSItem*'s contents.

```

⟨Pop a definition item 1444⟩ +≡
itDefFunc: begin nLastWSItem↑.nContent ← new(FunctorDefinitionPtr, Init(gPatternPos,
    gRedefinitions, FunctorPatternPtr(gPattern), gSpecification, gDefiningWay, gDefiniens));
end;

```

1446. Pop an attribute definition. We just need to add an *AttributeDefinition* object to the caller's *nLastWSItem*'s contents.

```

⟨Pop a definition item 1444⟩ +≡
itDefAttr: begin nLastWSItem↑.nContent ← new(AttributeDefinitionPtr, Init(gPatternPos,
    gRedefinitions, AttributePatternPtr(gPattern), gDefiniens));
end;

```

1447. Pop a predicate definition. We just need to add a *PredicateDefinition* object to the caller's *nLastWSItem*'s contents.

```

⟨Pop a definition item 1444⟩ +≡
itDefPred: begin nLastWSItem↑.nContent ← new(PredicateDefinitionPtr, Init(gPatternPos,
    gRedefinitions, PredicatePatternPtr(gPattern), gDefiniens));
end;

```

1448. Popping a structure definition. We just need to add a *StructureDefinition* object to the caller's *nLastWSItem*'s contents.

```

⟨Global variables introduced in parseraddition.pas 1382⟩ +≡
gConstructorNr: integer;

```

```

1449. ⟨Local variables for parser additions 1389⟩ +≡
gParams: PList;
gStructFields: PList;

```

```

1450. ⟨Pop a definition item 1444⟩ +≡
itDefStruct: begin nLastWSItem↑.nContent ← new(StructureDefinitionPtr, Init(gPatternPos,
    gStructPrefixes, gConstructorNr, gParams, gStructFields));
end;

```

1451. Pop a cluster registration item. A “cluster” registration (i.e., a existential, conditional, or functor registration) adds to the caller’s *nLastWSItem*’s contents a new cluster object (of appropriate kind). The *gClusterSort* is populated when the Parser finishes a cluster registration when invoking *extItemObj.FinishAntecedent* (§1461) or similar methods.

The *gClusterTerm* is populated in the *extItemObj.FinishClusterTerm* method (§1462).

⟨Local variables for parser additions 1389⟩ +≡
gAntecedent, *gConsequent*: *PList*;
gClusterTerm: *TermPtr*;

1452. ⟨Pop a registration item 1452⟩ ≡
itCluster: **begin case** *gClusterSort* **of**
 ExistentialRegistration: **begin**
 nLastWSItem↑.*nContent* ← *new*(*EClusterPtr*, *Init*(*nItemPos*, *gConsequent*, *gLastType*));
 include(*gCorrectnessConditions*, *syExistence*)
 end;
 ConditionalRegistration: **begin** *nLastWSItem*↑.*nContent* ← *new*(*CClusterPtr*, *Init*(*nItemPos*,
 gAntecedent, *gConsequent*, *gLastType*)); *include*(*gCorrectnessConditions*, *syCoherence*);
 end;
 FunctorialRegistration: **begin** *nLastWSItem*↑.*nContent* ← *new*(*FClusterPtr*, *Init*(*nItemPos*,
 gClusterTerm, *gConsequent*, *gLastType*)); *include*(*gCorrectnessConditions*, *syCoherence*);
 end;
endcases;
end;

See also section 1455.

This code is used in section 1430.

1453. Pop a registration item. For an *identify* or *reduce* registration, we assign the content of the caller’s *nLastWSItem* a new *IdentifyRegistration* (resp., *ReduceRegistration*) object. Identify registrations use the *gIdentifyEqLocList* local variable, while the reduction registrations use the *gLeftTermInReduction* module-wide variable.

⟨Global variables introduced in *parseraddition.pas* 1382⟩ +≡
gLeftTermInReduction: *TermPtr*;

1454. ⟨Local variables for parser additions 1389⟩ +≡
gIdentifyEqLocList: *PList*;

1455. ⟨Pop a registration item 1452⟩ +≡
itIdentify: **begin** *nLastWSItem*↑.*nContent* ← *new*(*IdentifyRegistrationPtr*, *Init*(*nItemPos*, *gNewPattern*,
 gPattern, *gIdentifyEqLocList*)); *include*(*gCorrectnessConditions*, *syCompatibility*);
end;
itReduction: **begin** *nLastWSItem*↑.*nContent* ← *new*(*ReduceRegistrationPtr*, *Init*(*nItemPos*,
 gLeftTermInReduction, *gLastTerm*)); *include*(*gCorrectnessConditions*, *syReducibility*);
end;
itPropertyRegistration: *SethoodRegistrationPtr*(*nLastWSItem*↑.*nContent*)↑.*nJustification* ← *nInference*;

1456. Check linkages are valid. When popping an item, we should check if the block containing the caller is *nLinked*. If so, flag a “178” error and assign *nLinked* \leftarrow *false*. Update the block’s *nLinkAllowed* depending on the caller’s *nLinkable* field. But if the Parser is in panic mode, the containing block’s *nLinkAllowed* and *nLinkProhibited* are both assigned to false. [[This configuration appears to encode a particular state which feels a bit of a “kludge” to me...]]

```

⟨ Check the popped item’s linkages are valid 1456 ⟩ ≡
  with extBlockPtr(gBlockPtr)↑ do
    begin if nLinked then
      begin Error(nLinkPos, 178); nLinked  $\leftarrow$  false end;
      nLinkAllowed  $\leftarrow$  nLinkable; nLinkProhibited  $\leftarrow$  ¬nLinkable;
    if ¬StillCorrect then
      begin nLinkAllowed  $\leftarrow$  false; nLinkProhibited  $\leftarrow$  false end;
    end

```

This code is used in section 1429.

Subsection 23.2.3. Registrations and notations

1457. Processing synonyms. We need to update the *gNewPatternPos* and *gNewPattern* global variables when processing a synonym.

```

  define process_notation_item ≡ gNewPatternPos  $\leftarrow$  gPatternPos; gNewPattern  $\leftarrow$  gPattern
⟨ Extended item implementation 1406 ⟩ +≡
procedure extItemObj.ProcessModeSynonym;
  begin process_notation_item; end;
procedure extItemObj.ProcessAttrSynonym;
  begin process_notation_item; end;
procedure extItemObj.ProcessAttrAntonym;
  begin process_notation_item; end;
procedure extItemObj.ProcessPredSynonym;
  begin process_notation_item; end;
procedure extItemObj.ProcessPredAntonym;
  begin process_notation_item; end;
procedure extItemObj.ProcessFuncSynonym;
  begin process_notation_item; end;

```

1458. Starting attributes. This is used when the Parser encounters a cluster registration (§1898). The *gAttrColl* is populated in the *extSubexpObj.CompleteAdjectiveCluster* (§1578) method.

```

⟨ Local variables for parser additions 1389 ⟩ +≡
gAttrColl: PList;

```

```

1459. ⟨ Extended item implementation 1406 ⟩ +≡
procedure extItemObj.StartAttributes;
  begin gAttrColl  $\leftarrow$  new(PList, Init(6));
  end;

```

1460. Starting a sentence. We just need to populate the caller's $nPropPos$, assigning to it the current position of the Parser.

⟨Extended item implementation 1406⟩ $\vdash \equiv$
procedure *extItemObj.StartSentence*;
 begin $nPropPos \leftarrow CurPos$;
 end;

1461. Processing conditional registration. This populates the $gClusterSort$ and the related global variables, as the Parser finishes parsing the antecedent and consequent to the cluster.

⟨Extended item implementation 1406⟩ $\vdash \equiv$
procedure *extItemObj.FinishAntecedent*;
 begin $gClusterSort \leftarrow ConditionalRegistration$; $gAntecedent \leftarrow gAttrColl$;
 end;
procedure *extItemObj.FinishConsequent*;
 begin $gConsequent \leftarrow gAttrColl$;
 end;

1462. Finishing a cluster. This populates the $gClusterSort$ and the $gClusterTerm$.

⟨Extended item implementation 1406⟩ $\vdash \equiv$
procedure *extItemObj.FinishClusterTerm*;
 begin $gClusterSort \leftarrow FunctorialRegistration$; $gClusterTerm \leftarrow gLastTerm$;
 end;

1463. Identify registration. Schematically, we have the registration statement look like (using global variable names for the subexpressions):

identify $\langle gNewPattern \rangle$ **with** $\langle gPattern \rangle$ [**when** $\langle gIdentifyEqLocList \rangle$];

We store the first pattern in the $gNewPattern$ global variable, then the second pattern in the $gPattern$ global variable. Completing the identify registration will check if the current word is “when” and, if so, start a list of loci equalities.

⟨Extended item implementation 1406⟩ $\vdash \equiv$
procedure *extItemObj.StartFuncIdentify*;
 begin end;
procedure *extItemObj.ProcessFuncIdentify*;
 begin $gNewPatternPos \leftarrow gPatternPos$; $gNewPattern \leftarrow gPattern$;
 end;
procedure *extItemObj.CompleteFuncIdentify*;
 begin $gIdentifyEqLocList \leftarrow \text{nil}$;
 if $CurWord.Kind = sy_When$ **then** $gIdentifyEqLocList \leftarrow new(PList, Init(0))$;
 end;

1464. “Reduces to” registrations. Recall, these schematically look like

reduce $\langle gLeftLocus \rangle$ **to** $\langle Locus \rangle$;

Mizar will populate $gLeftLocus$. The gambit will be to treat this as a functor pattern; i.e., the $gLeftLocus$ will be used to populate $gNewPattern$ in the method *extItemObj.FinishFunctorPattern* (§1503).

⟨Local variables for parser additions 1389⟩ $\vdash \equiv$
 $gLeftLocus: LocusPtr$;

1465. $\langle \text{Extended item implementation } 1406 \rangle + \equiv$
procedure *extItemObj.ProcessLeftLocus*;
 begin *gLeftLocus* \leftarrow *new*(*LocusPtr*, *Init*(*CurPos*, *GetIdentifier*));
 end;
procedure *extItemObj.ProcessRightLocus*;
 begin *gIdentifyEqLociList.Insert*(*new*(*LociEqualityPtr*, *Init*(*PrevPos*, *gLeftLocus*, *new*(*LocusPtr*,
 Init(*CurPos*, *GetIdentifier*))));
 end;
procedure *extItemObj.StartFuncReduction*;
 begin end;
procedure *extItemObj.ProcessFuncReduction*;
 begin *gNewPatternPos* \leftarrow *gPatternPos*; *gLeftTermInReduction* \leftarrow *gLastTerm*;
 end;

Subsection 23.2.4. Processing definitions

1466. The terminology used by the Parser appears to be (§§1782 *et seq.*):

let $\langle \text{Fixed Variables} \rangle$;

and

consider $\langle \text{Fixed Variables} \rangle$ **such that**...

This would mean that we would have “fixed variables” refer to a list of qualified segments. We remind the reader of the grammar

$$\begin{aligned} \langle \text{Fixed-Variables} \rangle &::= \langle \text{Implicitly-Qualified-Variables} \rangle \{ ", " \langle \text{Fixed-Variables} \rangle \} \\ &\quad | \langle \text{Explicitly-Qualified-Variables} \rangle \{ ", " \langle \text{Fixed-Variables} \rangle \} \\ \langle \text{Implicitly-Qualified-Variables} \rangle &::= \langle \text{Variables} \rangle \\ \langle \text{Explicitly-Qualified-Variables} \rangle &::= \langle \text{Qualified-Segment} \rangle \{ ", " \langle \text{Qualified-Segment} \rangle \} \\ \langle \text{Qualified-Segment} \rangle &::= \langle \text{Variables} \rangle \langle \text{Qualification} \rangle \\ \langle \text{Variables} \rangle &::= \langle \text{Variable} \rangle \{ ", " \langle \text{Variable} \rangle \} \\ \langle \text{Qualification} \rangle &::= ("be" | "being") \langle \text{Type} \rangle \end{aligned}$$

The “fixed variables” routine in the Parser will parse a comma-separated list of qualified variables.

CAUTION: The grammar in the `syntax.txt` file is actually more strict than this, because it actually states the following:

$$\langle \text{Loci-Declaration} \rangle ::= \text{"let"} \langle \text{Qualified-Variables} \rangle [\text{"such"} \langle \text{Conditions} \rangle] ;$$

The grammar for a qualified segment *requires* implicitly qualified variables appear at the very end.

$\langle \text{Extended item implementation } 1406 \rangle + \equiv$
procedure *extItemObj.StartFixedVariables*;
 begin *gQualifiedSegmentList* \leftarrow *new*(*PList*, *Init*(0));
 end;

1467. $\langle \text{Global variables introduced in parseraddition.pas } 1382 \rangle + \equiv$
gQualifiedSegment: *MList*;
gSegmentPos: *Position*;

1468. Fixed segments. This refers to each “explicitly qualified segment” or “implicitly qualified segment” appearing in the fixed variables portion. The fixed segments are separated by commas.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartFixedSegment;
  begin gQualifiedSegment.Init(0); gSegmentPos ← CurPos;
  end;
```

1469. When parsing fixed variables, and the Parser has just entered the loop to parse fixed variables, this function will be invoked.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessFixedVariable;
  begin gQualifiedSegment.Insert(new(VariablePtr, Init(CurPos, GetIdentifier)));
  end;
```

1470. This “clears the cache” for assigning the type in an explicitly qualified segment (appearing in a fixed variable segment).

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessBeing;
  begin gLastType ← nil;
  end;
```

1471. The last statement in the Parser loop when parsing “fixed variables” is to push the “fixed segment” onto the *gQualifiedSegmentList* global variable. There are two cases to consider: the implicitly qualified variables and the explicitly qualified variables.

The implicitly qualified case simply *moves* the pointers around “manually”, so we need to update every entry of *gQualifiedSegment.Items* to be **nil**. The explicitly qualified case moves the pointers around using the *MList* constructor, mutating *gQualifiedSegment* into a list of **nil** pointers.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishFixedSegment;
  var k: integer;
  begin if gLastType ≠ nil then { explicitly qualified case }
    begin gQualifiedSegmentList↑.Insert(new(ExplicitlyQualifiedSegmentPtr, Init(gSegmentPos,
      new(PList, MoveList(gQualifiedSegment)), gLastType))); gQualifiedSegment.DeleteAll;
    end
  else begin for k ← 0 to gQualifiedSegment.Count − 1 do
    begin gQualifiedSegmentList↑.Insert(new(ImplicitlyQualifiedSegmentPtr,
      Init(VariablePtr(gQualifiedSegment.Items↑[k]↑.nVarPos, gQualifiedSegment.Items↑[k])));
      gQualifiedSegment.Items↑[k] ← nil;
    end;
  end;
  gQualifiedSegment.Done;
  end;
```

1472. When we finish parsing fixed variables, we need to “unset” the *gPremises* global variable. The Parser will either be looking at a semicolon token or at “**such** ⟨*Conditions*⟩”. The reader should note that *gSuchThatOcc* is not used in the Parser, nor anywhere else in Mizar. But we recall (§1442) the *gSuchPos* is used when popping a **let** statement.

⟨Local variables for parser additions 1389⟩ +≡

```
gSuchThatOcc: boolean; { not used }
```

1473. \langle Extended item implementation 1406 $\rangle + \equiv$

```
procedure extItemObj.FinishFixedVariables;
  begin gSuchThatOcc  $\leftarrow$  CurWord.Kind = sy_Such; gSuchPos  $\leftarrow$  CurPos; gPremises  $\leftarrow$  nil;
  end;
```

1474. When the Parser encounters the statement:

let \langle Fixed-Variables \rangle **such that** \langle Assumption \rangle ;

The first things it does when encountering the “**such**” token is move to the next token (“**that**”) and then invoke the *StartAssumption* method. We should allocate a fresh list for *gPremises* and mark the position of the “**that**” token.

\langle Extended item implementation 1406 $\rangle + \equiv$

```
procedure extItemObj.StartAssumption;
  begin gPremises  $\leftarrow$  new(PList, Init(0)); gThatPos  $\leftarrow$  CurPos;
  end;
```

1475. Finishing an assumption will update the global variable *gBlockPtr*’s field reflecting it has assumptions.

\langle Extended item implementation 1406 $\rangle + \equiv$

```
procedure extItemObj.FinishAssumption;
  begin ExtBlockPtr(gBlockPtr)↑.nHasAssumptions  $\leftarrow$  true;
  end;
```

1476. When the Mizar Parser has encountered

assume that \langle Conditions \rangle ;

we start a collective assumption when the Parser has just encountered the “**that**” token. As with the “**let** statement with assumptions”, we need to allocate a new list for *gPremises* and assign the *gThatPos* to the current position.

\langle Extended item implementation 1406 $\rangle + \equiv$

```
procedure extItemObj.StartCollectiveAssumption;
  begin gPremises  $\leftarrow$  new(PList, Init(0)); gThatPos  $\leftarrow$  CurPos;
  end;
```

1477. Processing copula in a definition. When defining a (nonexpandable) mode, a functor, a predicate, or an attribute, we have

$$\langle Pattern \rangle \text{ means } \langle Expression \rangle;$$

or

$$\langle Pattern \rangle \text{ equals } \langle Expression \rangle;$$

The expression may or may not be labeled, we may or may not have the definition-by-cases. Whatever the situation, we should initialize the variables describing the definiens:

- the *gDefLabId* should be reset to zero (and populated in the *ProcessDefLabel* method);
- the *gDefLabPos* should be reset to the current position (and populated in the *ProcessDefLabel* method);
- the *gDefiningWay* should be assigned to *dfMeans* or *dfEquals* depending on the copula used in the definition;
- the *gOtherwise* pointer should be assigned to **nil**;
- the *gMeansPos* position should be assigned to the current position.

Following tradition in logic, we will refer to “means” and “equals” as the “**Copula**” in the definition.

\langle Global variables introduced in *parseraddition.pas* 1382 $\rangle + \equiv$
gDefLabId: integer;
gDefLabPos: Position;

1478. \langle Local variables for parser additions 1389 $\rangle + \equiv$
gOtherwise: PObject;

1479. \langle Extended item implementation 1406 $\rangle + \equiv$
procedure *extItemObj.ProcessMeans*;
 begin *gDefLabId* \leftarrow 0; *gDefLabPos* \leftarrow *CurPos*; *gDefiningWay* \leftarrow *dfMeans*; *gOtherwise* \leftarrow **nil**;
 gMeansPos \leftarrow *CurPos*
 end;
procedure *extItemObj.ProcessEquals*;
 begin *gDefLabId* \leftarrow 0; *gDefLabPos* \leftarrow *CurPos*; *gDefiningWay* \leftarrow *dfEquals*; *gOtherwise* \leftarrow **nil**;
 gMeansPos \leftarrow *CurPos*;
 end;

1480. When parsing a definition-by-cases, the cases are terminated with an “otherwise” keyword. Recall the grammar for such definitions looks like:

$$\langle Partial-Definiens-List \rangle \text{ "otherwise" } \langle Expression \rangle;$$

What happens depends on whether the definition uses “means” or “equals”: in the former case, we should update the *gOtherwise* pointer to be the *gLastFormula*; in the latter case, we should update the *gOtherwise* to be the *gLastTerm*.

\langle Extended item implementation 1406 $\rangle + \equiv$
procedure *extItemObj.FinishOtherwise*;
 begin if *gDefiningWay* = *dfEquals* **then** *gOtherwise* \leftarrow *gLastTerm*
 else *gOtherwise* \leftarrow *gLastFormula*;
 end;

1481. Starting a definiens should mutate the *it_Allowed* global variable to be equal to the caller's *nItAllowed* field. The *it_Allowed* global variable is toggled on and off when the Parser encounters “guards” in conditional definitions, whereas the *nItAllowed* fields reflects whether the sort of definition allows “it” in the definiens.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartDefiniens;
  begin it_Allowed ← nItAllowed;
  end;
```

1482. “Guards” refers to the conditions in a definition-by-cases. Specifically, we have

$$\langle \textit{Partial-Definiens} \rangle ::= \langle \textit{Expression} \rangle \text{ "if" } \langle \textit{Guard-Formula} \rangle$$

be the grammar for one particular case. We have a comma-separated list of partial definiens, so whenever the Parser (a) first encounters the “if” keyword in a definiens, or (b) has already encountered the “if” keyword and now has encountered a comma — these are the two cases to start a new guard.

⟨Local variables for parser additions 1389⟩ +≡

gPartDef: *PObject*;

1483. ⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartGuard;
  begin if gPartialDefs = nil then gPartialDefs ← new(PList, Init(0));
  it_Allowed ← false;
  if gDefiningWay = dfMeans then gPartDef ← gLastFormula
  else gPartDef ← gLastTerm;
  end;
```

1484. After parsing a formula, then the Parser will invoke *FinishGuard*. This will append to *gPartialDefs* a new partial definiens.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishGuard;
  begin it_Allowed ← nItAllowed;
  case gDefiningWay of
    dfMeans: gPartialDefs.Insert(new(PartDefPtr, Init(new(DefExpressionPtr, Init(exFormula, gPartDef)), gLastFormula)));
    dfEquals: gPartialDefs.Insert(new(PartDefPtr, Init(new(DefExpressionPtr, Init(exTerm, gPartDef)), gLastFormula)));
  endcases;
  end;
```

1485. Recall for functor definitions we have something like:

```
func  $\langle Pattern \rangle \rightarrow \langle Type \rangle$  ( means | equals ) ...
```

Similarly, nonexpandable modes look like

```
mode  $\langle Pattern \rangle \rightarrow \langle Type \rangle$  means ...
```

The “ $\rightarrow \langle Type \rangle$ ” is called the [type] *specification* for the definition. We should update the *gSpecification* global variable to point to whatever the last type parsed was — which is stored in the *gLastType* global variable.

```
 $\langle$  Extended item implementation 1406  $\rangle + \equiv$   
procedure extItemObj.FinishSpecification;  
  begin gSpecification  $\leftarrow$  gLastType;  
  end;
```

1486. “Construction type” is the term used by the Parser for “nonexpandable modes”. They, too, have a type specification. The *FinishConstructionType* populates the *gSpecification* global variable with this type.

```
 $\langle$  Extended item implementation 1406  $\rangle + \equiv$   
procedure extItemObj.FinishConstructionType;  
  begin gSpecification  $\leftarrow$  gLastType;  
  end;
```

1487. Expandable mode definitions, after encountering the “is” keyword, invokes the *StartExpansion* method. This just ensures there is no definiens, and the *gExpandable* global variable is assigned to “true”.

```
 $\langle$  Extended item implementation 1406  $\rangle + \equiv$   
procedure extItemObj.StartExpansion;  
  begin if gRedefinitions then ErrImm(271);  
    nDefiniensProhibited  $\leftarrow$  true; gExpandable  $\leftarrow$  true;  
  end;
```

1488. The Parser, when determining the pattern for an attribute (§1845), resets the state when starting to determine the pattern for the attribute. This is handled by the *StartAttribute* method.

We should remind the reader that attributes can only have arguments *to its left*.

```
 $\langle$  Global variables introduced in parseraddition.pas 1382  $\rangle + \equiv$   
gParamNbr: integer;
```

1489. \langle Local variables for parser additions 1389 $\rangle + \equiv$
gLocus: *LocusPtr*;

```
1490.  $\langle$  Extended item implementation 1406  $\rangle + \equiv$   
procedure extItemObj.StartAttributePattern;  
  begin gParamNbr  $\leftarrow$  0; gParams  $\leftarrow$  nil; gLocus  $\leftarrow$  new(LocusPtr, Init(CurPos, GetIdentifier));  
  end;
```

1491. Since an attribute can only have attributes to its left, it's pretty clear when the attribute pattern has been parsed: the Parser has found the attribute being defined. In that case (assuming we're not panicking), we should add the attribute format to the *gFormatsColl* dictionary and update the global variables.

⟨Extended item implementation 1406⟩ +≡

procedure *extItemObj.FinishAttributePattern*;

var *lFormatNr*: integer;

begin *lFormatNr* ← 0;

if (*CurWord.Kind* = *AttributeSymbol*) ∧ *stillcorrect* **then**

lFormatNr ← *gFormatsColl.CollectPrefixForm*(*ˆVˆ*, *CurWord.Nr*, *gParamNbr*);

gPatternPos ← *CurPos*; *gConstructorNr* ← *CurWord.Nr*;

gPattern ← *new*(*AttributePatternPtr*, *Init*(*gPatternPos*, *gLocus*, *gConstructorNr*, *gParams*));

end;

1492. A mode definition may include a “sethood” property. This particular function is used when registering sethood in a registration block.

⟨Extended item implementation 1406⟩ +≡

procedure *extItemObj.FinishSethoodProperties*;

begin

nLastWSItem↑.*nContent* ← *new*(*SethoodRegistrationPtr*, *Init*(*nItemPos*, *gPropertySort*, *gLastType*));

end;

1493. We remind the reader the grammar for a mode pattern

$$\langle \textit{Mode-Pattern} \rangle ::= \langle \textit{Mode-Symbol} \rangle [\textit{"of"} \langle \textit{Loc} \rangle]$$

The loci parameters can only appear *after* the mode symbol (and before the “of” reserved keyword). Starting a mode pattern should reset the relevant global variables.

⟨Extended item implementation 1406⟩ +≡

procedure *extItemObj.StartModePattern*;

begin *gParamNbr* ← 0; *gParams* ← **nil**; *gPatternPos* ← *CurPos*; *gConstructorNr* ← *CurWord.Nr*;

end;

1494. Finishing a mode pattern should build a new *ModePatternObj*, and store it in the *gPattern* global variable. And if we are not panicking, we should add it to the *gFormatsColl* dictionary.

⟨Extended item implementation 1406⟩ +≡

procedure *extItemObj.FinishModePattern*;

var *lFormatNr*: integer;

begin *lFormatNr* ← 0;

if *StillCorrect* **then** *lFormatNr* ← *gFormatsColl.CollectPrefixForm*(*ˆMˆ*, *gConstructorNr*, *gParamNbr*);

gPattern ← *new*(*ModePatternPtr*, *Init*(*gPatternPos*, *gConstructorNr*, *gParams*));

end;

1495. When Parser starts parsing a new predicate pattern, we should reset the relevant global variables.

⟨Extended item implementation 1406⟩ +≡

procedure *extItemObj.StartPredicatePattern*;

begin *gParamNbr* ← 0; *gParams* ← **nil**;

end;

1496. When the Parser tries to parse a “predicative formula” (i.e., a formula involving a predicate) — including predicate patterns — the first thing it does is invoke this *ProcessPredicateSymbol* method. This resets the global variables needed to populate the arguments to the predicate in the formula.

⟨Global variables introduced in *parseraddition.pas* 1382⟩ +≡
gLeftLocaNbr: *integer*;

1497. ⟨Local variables for parser additions 1389⟩ +≡
gLeftLoc: *PList*;

1498. ⟨Extended item implementation 1406⟩ +≡
procedure *extItemObj.ProcessPredicateSymbol*;
 begin *gPatternPos* ← *CurPos*; *gLeftLocaNbr* ← *gParamNbr*; *gLeftLoc* ← *gParams*; *gParamNbr* ← 0;
 gParams ← **nil**; *gConstructorNr* ← *CurWord.Nr*;
 end;

1499. Finishing a predicate pattern will create a new *PredicatePattern* object, update the *gPattern* global variable to point to it, and (if the Parser is not panicking) add the predicate’s format to the *gFormatsColl* dictionary.

⟨Extended item implementation 1406⟩ +≡
procedure *extItemObj.FinishPredicatePattern*;
 var *lFormatNr*: *integer*;
 begin *lFormatNr* ← 0;
 if *StillCorrect* **then**
 lFormatNr ← *gFormatsColl.CollectPredForm(gConstructorNr, gLeftLocaNbr, gParamNbr)*;
 gPattern ← *new(PredicatePatternPtr, Init(gPatternPos, gLeftLoc, gConstructorNr, gParams))*;
 end;

1500. Functor patterns a bit trickier. When starting one, what should occur depends on the type of functor being defined. Specifically, we handle brackets differently than other functors, and within the brackets we handle braces (i.e., definitions like $\{x_1, \dots, x_n\}$) differently than square brackets $[x_1, \dots, x_n]$ differently than everything other functor bracket.

In all cases, even non-bracket functors, we need to reset the *gParamNbr* and *gParams* global variables so they may be populated correctly.

⟨Global variables introduced in *parseraddition.pas* 1382⟩ +≡
gSubItemKind: *TokenKind*;

1501. ⟨Extended item implementation 1406⟩ +≡
procedure *extItemObj.StartFunctorPattern*;
 begin *gPatternPos* ← *CurPos*; *gSubItemKind* ← *CurWord.Kind*;
 case *CurWord.Kind* **of**
 LeftCircumfixSymbol: *gConstructorNr* ← *CurWord.Nr*;
 sy_LeftSquareBracket: **begin** *gSubItemKind* ← *LeftCircumfixSymbol*; *gConstructorNr* ← *SquareBracket*
 end;
 sy_LeftCurlyBracket: **begin** *gSubItemKind* ← *LeftCircumfixSymbol*; *gConstructorNr* ← *CurlyBracket*
 end;
 othercases *gConstructorNr* ← 0;
 endcases; *gParamNbr* ← 0; *gParams* ← **nil**;
 end;

1502. For “non-bracket” functors (i.e., infix operators), the functor pattern is processed by (1) getting the left parameters, (2) processing the functor symbol, (3) getting the right parameters. This function is precisely step (2).

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessFunctorSymbol;
  begin gPatternPos ← CurPos;
  if CurWord.Kind = InfixOperatorSymbol then
    begin gSubItemKind ← InfixOperatorSymbol; gConstructorNr ← CurWord.Nr;
    gLeftLocaNbr ← gParamNbr; gLeftLocs ← gParams; gParamNbr ← 0; gParams ← nil;
    end;
  end;
```

1503. When defining a bracket functor pattern, we add a new bracket format to the *gFormatsColl* dictionary, and then set *gPattern* to a newly allocated Bracket pattern.

When defining an infix functor, we add a new functor format to the *gFormatsColl* dictionary, and then we set the *gPattern* to a newly allocated infix functor pattern.

The “other cases” constructs an infix functor pattern, but does not add the form to the *gFormatsColl* dictionary.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishFunctorPattern;
  var lConstructorNr, lFormatNr: integer;
  begin lFormatNr ← 0;
  case gSubItemKind of
    LeftCircumfixSymbol: begin lConstructorNr ← CurWord.Nr;
      if StillCorrect then
        lFormatNr ← gFormatsColl.CollectBracketForm(gConstructorNr, lConstructorNr, gParamNbr, 0, 0);
        gPattern ← new(CircumfixFunctorPatternPtr, Init(gPatternPos, gConstructorNr, lConstructorNr,
          gParams));
        end;
      InfixOperatorSymbol: begin if StillCorrect then
        lFormatNr ← gFormatsColl.CollectFuncForm(gConstructorNr, gLeftLocaNbr, gParamNbr);
        gPattern ← new(InfixFunctorPatternPtr, Init(gPatternPos, gLeftLocs, gConstructorNr, gParams));
        end;
      othercases
        gPattern ← new(InfixFunctorPatternPtr, Init(gPatternPos, gLeftLocs, gConstructorNr, gParams));
      endcases;
  end;
```

1504. The Parser’s *ReadVisible* procedure begins by invoking this *StartVisible* method. The *ReadVisible* procedure occurs when getting most patterns.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartVisible;
  begin gParams ← new(PList, Init(0));
  end;
```

1505. The Parser iteratively calls its *GetVisible* (§1835) procedure when *ReadVisible* arguments in a pattern. The *GetVisible* procedure in turn invokes this *ProcessVisible*, which increments the number of parameters, and pushes a new *Locus* object onto the *gParams* stack.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessVisible;
  begin inc(gParamNbr);
  if gParams ≠ nil then gParams↑.Insert(new(LocusPtr, Init(CurPos, GetIdentifier)));
  end;
```

1506. Recall a structure definition, when it has ancestors, looks like

struct (⟨Ancestors⟩) ⟨Structure-Symbol⟩ ...

The ⟨Ancestors⟩ field is considered the “prefix” to the structure definition. The Parser parses a type (thereby populating the *gLastType* global variable), then invokes the *FinishPrefix* method, then iterates if it encounters a comma.

The *FinishPrefix* method pushes the *gLastType* global variable to the *gStructPrefixes* state variable.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishPrefix;
  begin gStructPrefixes.Insert(gLastType);
  end;
```

1507. ⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessStructureSymbol;
  var lFormatNr: integer;
  begin gConstructorNr ← 0; gPatternPos ← CurPos;
  if CurWord.Kind = StructureSymbol then gConstructorNr ← CurWord.Nr;
  lFormatNr ← gFormatsColl.CollectPrefixForm(‘J’, gConstructorNr, 1); gParamNbr ← 0;
  gParams ← nil;
  end;
```

1508. When the Parser has just finished parsing the ancestors to a structure, but has not parsed the visible arguments. Then the Parser prepares for reading the visible arguments and then the fields by invoking this method. This initializes the *gStructFields* state variable as well as the *gFieldsNbr* state variable.

⟨Global variables introduced in parseraddition.pas 1382⟩ +≡

gFieldsNbr: integer;

1509. ⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartFields;
  var lFormatNr: integer;
  begin lFormatNr ← gFormatsColl.CollectPrefixForm(‘L’, gConstructorNr, gParamNbr);
  in_AggrPattern ← true; gStructFields ← new(PList, Init(0)); gFieldsNbr ← 0;
  end;
```

1510. The Parser has just encountered the end structure bracket (“#”) token, so we want to add the format to the *gFormatsColl* dictionary.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishFields;
  var lFormatNr: integer;
  begin lFormatNr ← gFormatsColl.CollectPrefixForm(‘G’, gConstructorNr, gFieldsNbr);
  end;
```

1511. Recall that each field-segment looks like

$$\langle \textit{Field-Segment} \rangle ::= \langle \textit{Selector-Symbol} \rangle \{ ", " \} \langle \textit{Selector-Symbol} \rangle \langle \textit{Specification} \rangle$$

Before parsing the field-segment, the *StartAggrPattSegment* is invoked.

$\langle \text{Local variables for parser additions 1389} \rangle + \equiv$
gStructFieldsSegment: *PList*;
gSgmPos: *Position*;

1512. $\langle \text{Extended item implementation 1406} \rangle + \equiv$
procedure *extItemObj.StartAggrPattSegment*;
 begin *gStructFieldsSegment* \leftarrow *new(Plist, Init(0))*; *gSgmPos* \leftarrow *CurPos*;
 end;

1513. For each selector-symbol the Parser encounters, it invokes the *ProcessField*.

$\langle \text{Extended item implementation 1406} \rangle + \equiv$
procedure *extItemObj.ProcessField*;
 var *lFormatNr*: *integer*;
 begin *lFormatNr* \leftarrow *gFormatsColl.CollectPrefixForm*(`U' , *CurWord.Nr*, 1);
 gStructFieldsSegment. \uparrow .*Insert*(*new(FieldSymbolPtr, Init(CurPos, CurWord.Nr))*); *inc(gFieldsNbr)*;
 end;

1514. After each field has been parsed, the Parser invokes this method to update the *gStructFields* will push a new field segment object onto it.

$\langle \text{Extended item implementation 1406} \rangle + \equiv$
procedure *extItemObj.FinishAggrPattSegment*;
 begin *gStructFields.Insert*(*new(FieldSegmentPtr, Init(gSgmPos, gStructFieldsSegment, gLastType))*);
 end;

Subsection 23.2.5. Processing remaining statements

1515. **Processing schemes.** Most of these methods are used in parsing a scheme block (§1915). It will be useful to examine that function to see where these methods are invoked.

When the Parser starts a new scheme, several state variables need to be reset. The *gSchemeIdNr* is populated by the *GetIdentifier* (§1381) procedure, the *gSchemeIdPos* is assigned the current position, and the *gSchemeParams* should be allocated to an empty list.

$\langle \text{Extended item implementation 1406} \rangle + \equiv$
procedure *extItemObj.ProcessSchemeName*;
 begin *gSchemeIdNr* \leftarrow *GetIdentifier*; *gSchemeIdPos* \leftarrow *CurPos*;
 gSchemeParams \leftarrow *new(PList, Init(0))*;
 end;

1516. A scheme qualification segment looks like, for predicates:

$$\langle \text{Variable} \rangle \{ \text{ " , " } \langle \text{Variable} \rangle \} \text{ " [" } [\langle \text{Type-Expression-List} \rangle] \text{ "] "}$$

And for functors:

$$\langle \text{Variable} \rangle \{ \text{ " , " } \langle \text{Variable} \rangle \} \text{ " (" } [\langle \text{Type-Expression-List} \rangle] \text{ ") "}$$

When the comma-separated list of identifiers have all been read, but before either “(” or “[” has been discerned, the Parser invokes *StartSchemeQualification*.

This will assign the current word kind to *gSubItemKind*, and then initialize the *gTypeList* to 4 items.

⟨ Global variables introduced in `parseraddition.pas` 1382 ⟩ +≡
gTypeList: *MList*;

1517. ⟨ Extended item implementation 1406 ⟩ +≡
procedure *extItemObj.StartSchemeQualification*;
 begin *gSubItemKind* ← *CurWord.Kind*; *gTypeList.Init*(4);
 end;

1518. After the type-list has been parsed, but before the closing parentheses or bracket has been encountered, the Parser invokes the *FinishSchemeQualification* method. This assigns the current position to the *gSubItemPos*.

⟨ Global variables introduced in `parseraddition.pas` 1382 ⟩ +≡
gSubItemPos: *Position*;

1519. ⟨ Extended item implementation 1406 ⟩ +≡
procedure *extItemObj.FinishSchemeQualification*;
 begin *gSubItemPos* ← *CurPos*
 end;

1520. Starting a scheme segment describes the situation where we are *just about* to start parsing the comma-separated list of identifiers for the scheme parameters. This just assigns the current position to the *gSubItemPos*, then initializes *gSchVarIds* to 2 spots.

⟨ Global variables introduced in `parseraddition.pas` 1382 ⟩ +≡
gSchVarIds: *MList*;

1521. ⟨ Extended item implementation 1406 ⟩ +≡
procedure *extItemObj.StartSchemeSegment*;
 begin *gSubItemPos* ← *CurPos*; *gSchVarIds.Init*(2);
 end;

1522. After parsing the identifier for an entry in the comma-separated list of scheme variables, the Parser invokes *ProcessSchemeVariable* to add the recently parsed identifier to the *gSchVarIds* state variable.

⟨ Extended item implementation 1406 ⟩ +≡
procedure *extItemObj.ProcessSchemeVariable*;
 begin *gSchVarIds.Insert*(*new*(*VariablePtr*, *Init*(*CurPos*, *GetIdentifier*)));
 end;

1523. Once the list of scheme variables and their type specification has been parsed, then the Parser invokes the *FinishSchemeSegment* method. This just turns the *gSchVarIds* list into a Predicate segment or a Functor segment, using the type list the Parser just finished parsing.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishSchemeSegment;
  begin case gSubItemKind of
    sy_LeftParanthesis: begin gSchemeParams.Insert(new(FunctorSegmentPtr, Init(gSubItemPos,
      new(PList, MoveList(gSchVarIds)), new(PList, MoveList(gTypeList)), gLastType)));
    end;
    sy_LeftSquareBracket: begin gSchemeParams.Insert(new(SchemeSegmentPtr, Init(gSubItemPos,
      PredicateSegment, new(PList, MoveList(gSchVarIds)), new(PList, MoveList(gTypeList))));
    end;
  endcases;
end;
```

1524. The “scheme thesis” is the formula statement of the scheme. Informally, a scheme looks like:

scheme {⟨Scheme-Parameters⟩} ⟨Scheme-thesis⟩ **"provided"** ⟨Scheme-premises⟩

This means the *gLastFormula* state variable contains the scheme’s thesis. But the Parser has not yet started the list of premises. This is when the Parser invokes the *FinishSchemeThesis* method, which assigns the *gLastFormula* to *gSchemeConclusion*, then allocates a new empty list for the *gSchemePremises*.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishSchemeThesis;
  begin gSchemeConclusion ← gLastFormula; gSchemePremises ← new(Plist, Init(0));
  end;
```

1525. The premises for a scheme consists of finitely many formulas separated by “**and**” keywords. The Parser enters into a loop invoking this method *after* parsing the formula but *before* checking the next word is “**and**” (and iterating loop). We just need to push the formula onto the *gSchemePremises* list.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishSchemePremise;
  begin gSchemePremises↑.Insert(new(PropositionPtr, Init(nLabel, gLastFormula, nPropPos)));
  end;
```

1526. Reserved variables. These methods are invoked only when the Parser parses a reservation (§1911). A “reservation segment” refers to the comma-separated list of variables and the type.

Starting a reservation segment allocates a new (empty) list for *gResIdents*, and assigns the *gResPos* to the current position. Each variable encountered in the comma-separated list of variables is appended to the *gResIdents* list using the *ProcessReservedIdentifier* method.

Mizar treats each reservation segment as a separate statement. So there is no difference between:

```
reserve G for Group, x,y,z for Element of G;
...and...
```

```
reserve G for Group;
reserve x,y,z for Element of G;
```

Finishing a reservation mutates both the *gLastWSItem* and *gLastWSBlock* global variables. Specifically, we allocate a new reservation *Item*, then update *gLastWSItem* to point to it. The caller’s *nLastWSItem* is updated to point to it, too. We assign the content of this newly allocated reservation *Item* based on the *gResIdents* list. We insert this *Item* to the end of the *gLastWSBlock*’s items.

⟨Global variables introduced in *parseraddition.pas* 1382⟩ +≡
gResIdents: *PList*;
gResPos: *Position*;

1527. ⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartReservationSegment;
begin gResIdents ← new(Plist, Init(0)); gResPos ← CurPos;
end;
```

```
procedure extItemObj.ProcessReservedIdentifier;
begin gResIdents↑.Insert(new(VariablePtr, Init(CurPos, GetIdentifier)));
end;
```

```
procedure extItemObj.FinishReservationSegment;
begin gLastWSItem ← gWsTextProper↑.NewItem(itReservation, gResPos);
nLastWSItem ← gLastWSItem;
gLastWSItem↑.nContent ← new(ReservationSegmentPtr, Init(gResIdents, gLastType));
gLastWSItem↑.nItemEndPos ← PrevPos; gLastWSBlock↑.nItems.Insert(gLastWSItem);
end;
```

1528. Both “defpred” and “deffunc” invokes *StartPrivateDefiniendum* to initialize the *gTypeList*, store the identifier in the *gPrivateId*, and assign the current position to the *gPrivateIdPos*. Further, *dolAllowed* is toggled to *true* — placeholder variables are going to be allowed in the type declarations of the private functor or private predicate (for example “defpred Foo[set, Element of \$1]”).

⟨Global variables introduced in *parseraddition.pas* 1382⟩ +≡
gPrivateId: *Integer*;
gPrivateIdPos: *Position*;

1529. ⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartPrivateDefiniendum;
begin gPrivateId ← GetIdentifier; gPrivateIdPos ← CurPos; dolAllowed ← true; gTypeList.Init(4);
end;
```

1530. Reading a “type list” (for scheme parameters or for private definitions) loops over reading a type, then pushing it onto the *gTypeList*. The parser delegates that latter “push work” to the *FinishLocusType* method.

⟨Extended item implementation 1406⟩ +≡
procedure *extItemObj.FinishLocusType*;
 begin *gTypeList.Insert(gLastType)*;
 end;

1531. The life-cycle of expressions is a little convoluted. The *Item* will allocate a new *extExpression* object and assign it to the *gExpPtr*. Later, almost always, the *gExpPtr* will invoke a method to create a subexpression. This subexpression will be populated, then the *gLastTerm* (or *gLastFormula*) will be updated to point to this subexpression object. The expression object will be freed.

⟨Extended item implementation 1406⟩ +≡
procedure *extItemObj.CreateExpression*(*fExpKind* : *ExpKind*);
 begin *gExpPtr* ← *new*(*extExpressionPtr*, *Init*(*fExpKind*));
 end;

1532. Recall the “set” statement is of the form

$$\text{"set" } \langle \text{Variable} \rangle \text{"=" } \langle \text{Term} \rangle \{ \text{"," } \langle \text{Variable} \rangle \text{"=" } \langle \text{Term} \rangle \}$$

The Parser parses this as a loop of assignments of terms to identifiers. Before iterating, the Parser invokes the *FinishPrivateConstant* method. This allocates a new item for the constant definition, then assigns it to the *gLastWSItem* and to the caller’s *nLastWSItem* field. Then the content for the new item is allocated to be a constant definition object using the *VariablePtr* state variable and the *gLastTerm* state variable. The *gLastBlock* global variable pushes the new constant definition item to its contents.

⟨Extended item implementation 1406⟩ +≡
procedure *extItemObj.FinishPrivateConstant*;
 begin *gLastWSItem* ← *gWsTextProper*↑.*NewItem*(*itConstantDefinition*, *nItemPos*);
 nLastWSItem ← *gLastWSItem*; *gLastWSItem*↑.*nContent* ← *new*(*ConstantDefinitionPtr*,
 Init(*new*(*VariablePtr*, *Init*(*gPrivateIdPos*, *gPrivateId*)), *gLastTerm*));
 gLastWSItem↑.*nItemEndPos* ← *PrevPos*; *gLastWSBlock*↑.*nItems.Insert*(*gLastWSItem*);
 nItemPos ← *CurPos*;
 end;

1533. When the Parser is about to start parsing an assignment “⟨*Variable*⟩ = ⟨*Term*⟩” in a “set” statement, the Parser invokes this method. The caller assigns the *gPrivateId* state variable to be the result of *GetIdentifier*, and the *gPrivateIdPos* state variable to be the current position.

⟨Extended item implementation 1406⟩ +≡
procedure *extItemObj.StartPrivateConstant*;
 begin *gPrivateId* ← *GetIdentifier*; *gPrivateIdPos* ← *CurPos*;
 end;

1534. For a “defpred” and a “deffunc”, before parsing the definiens, we need to set the *dol_Allowed* global variable to true (to allow placeholder variables).

⟨Extended item implementation 1406⟩ +≡
procedure *extItemObj.StartPrivateDefiniens*;
 begin *dol_Allowed* ← *true*;
 end;

1535. After parsing the definiendum term for a “**deffunc**”, the Parser invokes this *FinishPrivateFuncDefinienition* method. This assigns the contents of the caller to a WSM private functor definition syntax tree.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishPrivateFuncDefinienition;
  begin nLastWSItem↑.nContent ← new(PrivateFunctorDefinitionPtr, Init(new(VariablePtr,
    Init(gPrivateIdPos, gPrivateId)), new(PList, MoveList(gTypeList)), gLastTerm));
  end;
```

1536. When finishing the definiendum formula for a “**defpred**”, the Parser invokes this *FinishPrivatePredDefinienition* method.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishPrivatePredDefinienition;
  begin nLastWSItem↑.nContent ← new(PrivatePredicateDefinitionPtr, Init(new(VariablePtr,
    Init(gPrivateIdPos, gPrivateId)), new(PList, MoveList(gTypeList)), gLastFormula));
  end;
```

1537. Reconsider statements.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessReconsideredVariable;
  begin gPrivateId ← GetIdentifier; gPrivateIdPos ← CurPos;
  end;
```

```
procedure extItemObj.FinishReconsideredTerm;
  begin gReconsiderList↑.Insert(new(TypeChangePtr, Init(Equating, new(VariablePtr,
    Init(gPrivateIdPos, gPrivateId)), gLastTerm)));
  end;
```

1538. This is invoked when parsing a private item which is a “**reconsider**” statement.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishDefaultTerm;
  begin gReconsiderList↑.Insert(new(TypeChangePtr, Init(VariableIdentifier, new(VariablePtr,
    Init(gPrivateIdPos, gPrivateId)), nil)));
  end;
```

1539. When the Parser finishes parsing a formula in “**consider** ⟨Segment⟩ **such that** ⟨Formula⟩ {**and** ⟨Formula⟩}”, the Parser invokes the *FinishCondition* method. This checks that *gPremises* has been allocated, then pushes a new labeled formula into it.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishCondition;
  begin if gPremises = nil then gPremises ← new(PList, Init(0));
  gPremises↑.Insert(new(PropositionPtr, Init(nLabel, gLastFormula, nPropPos)));
  end;
```

1540. In statements of the form

assume $\langle \text{Formula} \rangle$;

Or of the form

assume $\langle \text{Formula} \rangle$ **and** $\langle \text{Formula} \rangle$ **and** ... **and** $\langle \text{Formula} \rangle$;

After each formula parsed, the Parser invokes the *FinishHypothesis*. This just inserts a new labeled formula into the *gPremises* state variable, when the *gPremises* state variable is not **nil**.

$\langle \text{Extended item implementation 1406} \rangle + \equiv$

```
procedure extItemObj.FinishHypothesis;
  begin if gPremises  $\neq$  nil then
    gPremises $\uparrow$ .Insert(new(PropositionPtr, Init(nLabel, gLastFormula, nPropPos)));
  end;
```

1541. “Take” statements. For statements of the form

take $\langle \text{Variable} \rangle = \langle \text{Term} \rangle$;

The Parser invokes the *ProcessExemplifyingVariable* method, then parses the term, and then constructs the AST by invoking *FinishExemplifyingVariable*.

Finishing a “take” statement mutates both the *gLastWSItem* and the *gLastWSBlock* global variables.

$\langle \text{Extended item implementation 1406} \rangle + \equiv$

```
procedure extItemObj.ProcessExemplifyingVariable;
  begin gPrivateId  $\leftarrow$  GetIdentifier; gPrivateIdPos  $\leftarrow$  CurPos;
  end;
```

```
procedure extItemObj.FinishExemplifyingVariable;
  begin gLastWSItem  $\leftarrow$  gWsTextProper $\uparrow$ .NewItem(itExemplification, nItemPos);
  nLastWSItem  $\leftarrow$  gLastWSItem; gLastWSItem $\uparrow$ .nContent  $\leftarrow$  new(ExamplePtr, Init(new(VariablePtr,
    Init(gPrivateIdPos, gPrivateId)), gLastTerm)); gLastWSItem $\uparrow$ .nItemEndPos  $\leftarrow$  PrevPos;
  gLastWSBlock $\uparrow$ .nItems.Insert(gLastWSItem); nItemPos  $\leftarrow$  CurPos;
  end;
```

1542. In statements of the form

take $\langle Term \rangle$;

the Parser begins by invoking *StartExemplifyingTerm*, parses the term, then *FinishExemplifyingTerm*.

\langle Extended item implementation 1406 $\rangle + \equiv$

```
procedure extItemObj.StartExemplifyingTerm;
  begin if (CurWord.Kind = Identifier)  $\wedge$  extBlockPtr(gBlockPtr) $\uparrow$ .nInDiffuse  $\wedge$  ((AheadWord.Kind =
    sy_Comma)  $\vee$  (AheadWord.Kind = sy_Semicolon)) then
    begin gPrivateId  $\leftarrow$  GetIdentifier; gPrivateIdPos  $\leftarrow$  CurPos;
    end
  else gPrivateId  $\leftarrow$  0;
  end;

procedure extItemObj.FinishExemplifyingTerm;
  begin gLastWSItem  $\leftarrow$  gWsTextProper $\uparrow$ .NewItem(itExemplification, nItemPos);
  nLastWSItem  $\leftarrow$  gLastWSItem;
  if gPrivateId  $\neq$  0 then gLastWSItem $\uparrow$ .nContent  $\leftarrow$  new(ExamplePtr, Init(new(VariablePtr,
    Init(gPrivateIdPos, gPrivateId)), nil))
  else gLastWSItem $\uparrow$ .nContent  $\leftarrow$  new(ExamplePtr, Init(nil, gLastTerm));
  gLastWSItem $\uparrow$ .nItemEndPos  $\leftarrow$  PrevPos; gLastWSBlock $\uparrow$ .nItems.Insert(gLastWSItem);
  nItemPos  $\leftarrow$  CurPos;
  end;
```

1543. When the Parser examines the correctness conditions (§1869), it loops over the correctness conditions and justifications. Afterwards, it invokes the *ProcessCorrectness* method, which tests that the Parser is not current looking at a correctness keyword. Then it tests if *gCorrectnessConditions* is empty or *AxiomsAllowed* (in which case, correctness has been satisfies, so the Parser moves happily along). But if *gCorrectnessConditions* $\neq \emptyset$ or axioms are not allowed, then a 73 error is raised.

\langle Extended item implementation 1406 $\rangle + \equiv$

```
procedure extItemObj.ProcessCorrectness;
  begin if CurWord.Kind  $\neq$  sy_Correctness then
    if (gCorrectnessConditions  $\neq$  [])  $\wedge$   $\neg$ AxiomsAllowed then Error(gDefPos, 73);
  end;
```

1544. A “construction type” appears in a redefinition where the type is redefined. In such a situation, we need to add “coherence” as a correctness condition. The *StartConstructionType* handles this task.

\langle Extended item implementation 1406 $\rangle + \equiv$

```
procedure extItemObj.StartConstructionType;
  begin if gRedefinitions  $\wedge$  (CurWord.Kind = sy_Arrow) then
    include(gCorrectnessConditions, syCoherence);
  end;
```

1545. This is used in the Parser’s *ProcessLab* procedure. Really, all the work is being done here: the *nLabel* field of the caller is assigned to a newly allocated *Label* object.

\langle Extended item implementation 1406 $\rangle + \equiv$

```
procedure extItemObj.ProcessLabel;
  begin nLabelIdNr  $\leftarrow$  0; nLabelIdPos  $\leftarrow$  CurPos;
  if (CurWord.Kind = Identifier)  $\wedge$  (AheadWord.Kind = sy_Colon) then nLabelIdNr  $\leftarrow$  CurWord.Nr;
  nLabel  $\leftarrow$  new(LabelPtr, Init(nLabelIdNr, nLabelIdPos));
  end;
```

1546. A regular statement is either a “diffuse” statement (which occurs with the “now” keyword) or else it’s a “compact” statement.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartRegularStatement;
  begin if CurWord.Kind = sy_Now then nRegularStatementKind ← stDiffuseStatement
  else nRegularStatementKind ← stCompactStatement;
  end;
```

1547. If the Parser encounters a colon after the copula, then it invokes this method to construct a label for the Definiens.

⟨Global variables introduced in *parseraddition.pas* 1382⟩ +≡

gDefLabel: *LabelPtr*;

1548. ⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessDefiniensLabel;
  begin gDefLabId ← 0; gDefLabPos ← CurPos;
  if (CurWord.Kind = Identifier) ∧ (AheadWord.Kind = sy_Colon) then gDefLabId ← CurWord.Nr;
  gDefLabel ← new(LabelPtr, Init(gDefLabId, gDefLabPos));
  end;
```

1549. The Parser, having encountered “from” and a non-MML reference, tries to treat the identifier as the label for a scheme declared in the current article. The *nInference* field would be a *SchemeJustification* object, so we just populate its *nSchemeIdNr* and position fields.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessSchemeReference;
  begin if CurWord.Kind = Identifier then
    begin SchemeJustificationPtr(nInference)↑.nSchemeIdNr ← CurWord.Nr;
    SchemeJustificationPtr(nInference)↑.nSchemeInfPos ← CurPos;
    end;
  end;
```

1550. When a “by” refers to a theorem or definition from an article in the MML, the Parser invokes the *StartLibraryReference* method.

⟨Global variables introduced in *parseraddition.pas* 1382⟩ +≡

gTHEFileNr: *integer*;

1551. ⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartLibraryReferences;
  begin gTHEFileNr ← CurWord.Nr;
  end;
```

1552. The Parser has already encountered a “from” and then an MML article identifier. Before continuing to parse the scheme number, the Parser invokes this method to initialize the relevant state variables.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartSchemeLibraryReference;
  begin gTHEFileNr ← CurWord.Nr;
  end;
```

1553. For references to labels found in the article being processed (“private references”), this method is invoked.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessPrivateReference;
  begin SimpleJustificationPtr(nInference)↑.nReferences↑.Insert(new(LocalReferencePtr,
    Init(GetIdentifier, CurPos)));
  end;
```

1554. When using a definition from an MML article in a scheme reference (something like “from *MyScheme*(*ARTICLE:def* 5,...)”), well, the Parser stores this fact in a state variable *gDefinitional*. The *ProcessDef* method populates this state variable correctly.

⟨Global variables introduced in *parseraddition.pas* 1382⟩ +≡
gDefinitional: *boolean*;

1555. ⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessDef;
  begin gDefinitional ← (CurWord.Kind = ReferenceSort) ∧ (CurWord.Nr = ord(syDef))
  end;
```

1556. When accumulating the references in a Scheme-Justification, and a reference is from an MML article, *ProcessTheoremNumber* transforms it into a newly allocated reference object. The caller’s *nInference* then adds the newly allocated object to its *nReferences* collection.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessTheoremNumber;
  var lRefPtr: ReferencePtr;
  begin if CurWord.Kind ≠ Numeral then exit;
  if CurWord.Nr = 0 then
    begin ErrImm(146); exit
    end;
  if gDefinitional then lRefPtr ← new(DefinitionReferencePtr, Init(gTHEFileNr, CurWord.Nr, CurPos))
  else lRefPtr ← new(TheoremReferencePtr, Init(gTHEFileNr, CurWord.Nr, CurPos));
  SimpleJustificationPtr(nInference)↑.nReferences↑.Insert(lRefPtr);
  end;
```

1557. When a Scheme-Justification uses a local reference, the Parser delegates the work to the *Item*’s *ProcessSchemeNumber* method. This updates the caller’s *nInference* field.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.ProcessSchemeNumber;
  begin if CurWord.Kind ≠ Numeral then exit;
  if CurWord.Nr = 0 then
    begin ErrImm(146); exit
    end;
  with SchemeJustificationPtr(nInference)↑ do
    begin nSchFileNr ← gTHEFileNr; nSchemeIdNr ← CurWord.Nr; nSchemeInfPos ← PrevPos;
    end;
  end;
```

1558. This appears when the Parser starts its *Justification* (§1803) procedure, or in the *RegularStatement* (§1832) procedure.

This clears the *nInference*, reassigning it to the **nil** pointer.

For nested “**proof**” blocks, check if the ‘check proofs’ (“**::\$P+**”) pragma has been enabled — if so, just set the caller’s *nInference* to be a new Justification object with a ‘proof’ tag. Otherwise, we’re skipping the proofs, so set *nInference* to be the ‘skipped’ justification.

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartJustification;
  begin nInference ← nil;
  if CurWord.Kind = sy_Proof then
    begin if ProofPragma then nInference ← new(JustificationPtr, Init(infProof, CurPos))
    else nInference ← new(JustificationPtr, Init(infSkippedProof, CurPos))
    end;
  end;
```

1559. A simple justification is either a Scheme-Justification (“**from...**”), a Straightforward-Justification (“**by...**”), or...somethign else?

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.StartSimpleJustification;
  begin case CurWord.Kind of
    sy_From: nInference ← new(SchemeJustificationPtr, Init(CurPos, 0, 0));
    sy_By: with extBlockPtr(gBlockPtr)↑ do
      nInference ← new(StraightforwardJustificationPtr, Init(CurPos, nLinked, nLinkPos));
    othercases with extBlockPtr(gBlockPtr)↑ do
      nInference ← new(StraightforwardJustificationPtr, Init(PrevPos, nLinked, nLinkPos));
    endcases;
  end;
```

1560. We should update the *nInference* field’s sort to be *infError* when, well, the inference is an error (e.g., the Parser is in panic mode). We should set the *gBlockPtr*’s *nLinked* field to false when we just added a straightforward justification (or an erroneous justification).

```
define is_inference_error ≡ ¬StillCorrect ∨
  ((CurWord.Kind ≠ sy_Semicolon) ∧ (CurWord.Kind ≠ sy_DotEquals)) ∨
  ((nInference↑.nInfSort = infStraightforwardJustification) ∧ (byte(nLinked) >
    byte(nLinkAllowed))) ∨ ((nInference↑.nInfSort = infSchemeJustification) ∧
    (SchemeJustificationPtr(nInference)↑.nSchemeIdNr = 0))
```

⟨Extended item implementation 1406⟩ +≡

```
procedure extItemObj.FinishSimpleJustification;
  begin with extBlockPtr(gBlockPtr)↑ do
    begin if is_inference_error then nInference↑.nInfSort ← infError;
    end;
  if (nInference↑.nInfSort = infStraightforwardJustification) ∨ (nInference↑.nInfSort = infError) then
    extBlockPtr(gBlockPtr)↑.nLinked ← false;
  end;
```

1561. For iterative equalities, we should recall that it looks like

```
LHS = RHS ⟨Justification⟩
  .= RHS2
  .= ...;
```

This matters because, well, when the Parser has parsed “LHS = RHS ⟨Justification⟩”, the Parser believes it is a compact statement. Until the Parser looks at the next token, it does not know whether this is a Compact-Statement or an iterated equality. The *FinishCompactMethod* peeks at the token, and when the token is an iterated equality (“.=”) updates the caller’s fields as well as initialize the *gIterativeLastFormula*, *gIterativeSteps*, and *gInference* state variables. The *gBlockPtr* is updated to make its *nLinked* field false.

⟨Extended item implementation 1406⟩ +≡

procedure *extItemObj.FinishCompactStatement*;

begin if *CurWord.Kind* = *sy_DotEquals* **then**

begin *gIterativeLastFormula* ← *gLastFormula*; *nRegularStatementKind* ← *stIterativeEquality*;

extBlockPtr(*gBlockPtr*)↑.*nLinked* ← false; *gIterativeSteps* ← *new*(*PList*, *Init*(0));

gInference ← *nInference*;

end;

end;

1562. Every time the Parser encounters the “.=” token, it immediately invokes the *StartIterativeStep* method. This just updates the *gIterPos* state variable to the current position.

⟨Local variables for parser additions 1389⟩ +≡

gIterPos: *Position*;

1563. ⟨Extended item implementation 1406⟩ +≡

procedure *extItemObj.StartIterativeStep*;

begin *gIterPos* ← *CurPos*; **end**;

1564. Right before the Parser iterates the loop checking if “.=” is the next token for an iterative equation, the Parser invokes the *FinishIterativeStep* method. This just adds a new *IterativeStep* object, an AST node representing the preceding “.= RHS by ⟨Justification⟩”.

⟨Extended item implementation 1406⟩ +≡

procedure *extItemObj.FinishIterativeStep*;

begin *gIterativeSteps*↑.*Insert*(*new*(*IterativeStepPtr*, *Init*(*gIterPos*, *gLastTerm*, *nInference*)));

end;

1565. In a definition, after the Parser finishes parsing the definiens, we construct the AST node for it with the *FinishDefiniens* method.

For each copula (“means” and “equals”), the algorithm is the same: if we just had a definition-by-cases, then store the “otherwise” clause in *lExp* and assign the *gDefiniens* state variable to a newly allocated conditional definiens object. If the definiens is not a definition-by-cases (i.e., it’s a “simple” definition), then just assign *gDefiniens* a newly allocated *SimpleDefiniens* object.

For functor definitions (not redefinitions), the *gCorrectnessConditions* are assigned here.

⟨ Extended item implementation 1406 ⟩ +=

```

procedure extItemObj.FinishDefiniens;
  var lExp: DefExpressionPtr;
  begin case gDefiningWay of
    dfMeans:
      if gPartialDefs  $\neq$  nil then
        begin lExp  $\leftarrow$  nil;
        if gOtherwise  $\neq$  nil then lExp  $\leftarrow$  new(DefExpressionPtr, Init(exFormula, gOtherwise));
        gDefiniens  $\leftarrow$  new(ConditionalDefiniensPtr, Init(gMeansPos, gDefLabel, gPartialDefs, lExp))
        end
      else gDefiniens  $\leftarrow$  new(SimpleDefiniensPtr, Init(gMeansPos, gDefLabel, new(DefExpressionPtr,
        Init(exFormula, gLastFormula))));
    dfEquals:
      if gPartialDefs  $\neq$  nil then
        begin lExp  $\leftarrow$  nil;
        if gOtherwise  $\neq$  nil then lExp  $\leftarrow$  new(DefExpressionPtr, Init(exTerm, gOtherwise));
        gDefiniens  $\leftarrow$  new(ConditionalDefiniensPtr, Init(gMeansPos, gDefLabel, gPartialDefs, lExp))
        end
      else gDefiniens  $\leftarrow$  new(SimpleDefiniensPtr, Init(gMeansPos, gDefLabel, new(DefExpressionPtr,
        Init(exTerm, gLastTerm))));
  endcases;
  if  $\neg$ gRedefinitions  $\wedge$  (nItemKind = itDefFunc) then
    begin if gDefiningWay = dfMeans then gCorrectnessConditions  $\leftarrow$  [syExistence, syUniqueness]
    else if gDefiningWay = dfEquals then gCorrectnessConditions  $\leftarrow$  [syCoherence];
    end;
  end;

```

Section 23.3. EXTENDED SUBEXPRESSION CLASS

1566. Aside: refactoring. We should probably refactor a private procedure *PushTermStack* to push a new term onto the term stack, and a private function *PopTermStack* to return the top of the term stack (and mutate the term stack), and possibly a *ResetTermStack* procedure (which will clear the term stack and possibly the objects stored in it?).

We see that *TermNbr* is decremented when popping the *Term* stack (via *FinishTerm*); when *FinishQualifyingFormula* is invoked, it decrements the *TermNbr*; when *FinishAttributiveFormula* is invoked, it decrements the *TermNbr*; but these latter two methods can (and should) be refactored to use the *FinishTerm* to pop the term stack and decrement the *TermNbr* state variable.

Assigning the *TermNbr* occurs when *CreateArgs* method is invoked; the *InsertIncorrBasic* method resets the *TermNbr* to the *nTermBase*; the *ProcessAtomicFormula*, when a 157 error is raised, will reset the *TermNbr* to the *nTermBase*; when the constructor for an *extExpression* object is invoked, it resets the *TermNbr* to zero (which happens in the *extItem*’s *CreateExpression* method—which occurs frequently enough to be a worry).

The only time when the *TermNbr* is incremented is when we push a new term onto the *Term* stack.

1567. There is a comment in Polish “teraz jest to kolekcja MultipleTypeExp”, which Google translates to “now it is a MultipleTypeExp collection”. I have made this replacement in the code below, prefixed with a “+” sign (to distinguish it from the other comment already in English).

Also note: the *nRestriction* refers to the subformula in a universally quantified formula

for $\langle Variables \rangle$ **st** $\langle Restriction \rangle$ **holds** ...

```
define arg_type  $\equiv$  record Start, Length: integer;
  end
define func_type  $\equiv$  record Instance, SymPri: integer;
  FuncPos: Position;
  end
```

```

See also sections 1571, 1572, 1573, 1575, 1576, 1577, 1578, 1579, 1580, 1581, 1582, 1583, 1584, 1585, 1586, 1587, 1588, 1589, 1590, 1591, 1593, 1597, 1609, 1610, 1611, 1612, 1613, 1614, 1615, 1616, 1617, 1618, 1619, 1620, 1621, 1622, 1623, 1624, 1625, 1626, 1627, 1628, 1629, 1630, 1631, 1632, 1633, 1634, 1635, 1636, 1637, 1638, 1639, 1640, 1641, 1642, 1643, 1644, 1645, 1646, 1647, 1648, 1649, 1650, 1651, 1652, 1653, 1654, 1655, 1656, 1657, 1658, 1659, 1660, 1661, 1662, 1663, 1664, 1665, 1666, 1667, and 1668.

This code is used in section 1380.

1571. When the Parser is about to parse a stack of attributes, either in a registration or on a type, we need to initialize the appropriate state variables. We also need the caller's *nAttrCollection* to be initialized with an empty list.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```
procedure extSubexpObj.StartAttributes;
  begin nAttrCollection.Init(0); gLastType  $\leftarrow$  nil;
  end;
```

1572. When the Parser expects an adjective, and the caller is used to store the adjective or attribute, we need to check if it is negated. This handles it.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```
procedure extSubexpObj.ProcessNon;
  begin nNoneOcc  $\leftarrow$  CurWord.Kind = sy_Non; nNonPos  $\leftarrow$  CurPos;
  end;
```

1573. Pop arguments from term stack. This will take some parameter *aBase* and copy pointers to each element of *Term*[*aBase* .. *TermNbr*] into a new list. Then the *TermNbr* state variable is updated to be *aBase* - 1.

This means that executing "*list1* \leftarrow *CreateArgs*(*aBase*); *list2* \leftarrow *CreateArgs*(*aBase*);" will have *list2* = **nil**.

Bug: when *aBase* \leq 0, this will set *TermNbr* to a negative number.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```
function CreateArgs(aBase : integer): PList;
  var k: integer; lList: PList;
  begin lList  $\leftarrow$  new(PList, Init(TermNbr - aBase));
  for k  $\leftarrow$  aBase to TermNbr do lList.Insert(Term[k]);
  TermNbr  $\leftarrow$  aBase - 1; CreateArgs  $\leftarrow$  lList;
  end;
```

1574. The "process (singular) attribute" method is invoked in the "process (plural) attributes" procedure (§1725), and in the *ATTSubexpression* procedure (§1895). This method will be invoked when the Parser is looking at an attribute token.

When there is no format recorded for such an attribute, then a 175 error will be raised.

This will allocate a new Adjective object, store it in the *gLastAdjective* state variable, then append it to the *nAttrCollection* field of the caller.

\langle Global variables introduced in *parseraddition.pas* 1382 $\rangle + \equiv$

```
gLastAdjective: AdjectiveExpressionPtr;
```

1575. \langle Extended subexpression implementation 1570 $\rangle + \equiv$

```

procedure extSubexpObj.ProcessAttribute;
  var lFormatNr: integer;
  begin if CurWord.Kind = AttributeSymbol then
    begin
      lFormatNr  $\leftarrow$  gFormatsColl.LookUp_PrefixFormat(~V, CurWord.Nr, TermNbr - nTermBase + 1);
      if lFormatNr = 0 then { format not found! }
        begin gLastAdjective  $\leftarrow$  new(AdjectivePtr, Init(CurPos, 0, CreateArgs(nTermBase + 1)));
          Error(CurPos, 175)
        end
      else begin
        gLastAdjective  $\leftarrow$  new(AdjectivePtr, Init(CurPos, CurWord.Nr, CreateArgs(nTermBase + 1)));
        if nNoneOcc then gLastAdjective  $\leftarrow$  new(NegatedAdjectivePtr, Init(nNonPos, gLastAdjective));
        end;
      end
    else { needed for ATTSubexpression adjective cluster handling }
      begin gLastAdjective  $\leftarrow$  new(AdjectivePtr, Init(CurPos, 0, CreateArgs(nTermBase + 1)));
        end;
      nAttrCollection.Insert(gLastAdjective);
    end;

```

1576. These next next method is invoked before the Parser parses arguments for an attribute.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```

procedure extSubexpObj.StartAttributeArguments;
  begin nTermBase  $\leftarrow$  TermNbr;
  end;

```

1577. The next two methods are invoked after the Parser has finished parsing the arguments for an attribute.

I am confused why there is duplicate code here, and the naming conventions suggest the *FinishAttributeArguments* method should be preferred. ■

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```

procedure extSubexpObj.CompleteAttributeArguments;
  begin nSubexpPos  $\leftarrow$  CurPos; nRightArgBase  $\leftarrow$  TermNbr;
  end;

procedure extSubexpObj.FinishAttributeArguments;
  begin nSubexpPos  $\leftarrow$  CurPos; nRightArgBase  $\leftarrow$  TermNbr;
  end;

```

1578. This allocates a new list of pointers, moves the caller's *nAttrCollection* into the list, and updates the *gAttrColl* state variable to point at them.

Again, this should be named *FinishedAdjectiveCluster* to be consistent with the naming conventions seemingly adopted.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```

procedure extSubexpObj.CompleteAdjectiveCluster;
  begin gAttrColl  $\leftarrow$  new(PList, MoveList(nAttrCollection));
  end;

```

1579. When the Parser works its way through a registration block, check that the *TermNbr* points to not farther ahead than one more token ahead from the caller's *nTermBase* field. Raise an error if that happens.

This method is only invoked in the Parser module's the *RegisterCluster* (§1898) procedure.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.CompleteClusterTerm;
  begin if TermNbr − nTermBase > 1 then
    begin ErrImm(379); gLastTerm ← new(IncorrectTermPtr, Init(CurPos));
    end;
  end;
```

1580. A “simple term” appears to be a variable. This is used when the Parser parses an identifier as a closed term (§1696). The state variable *gLastTerm* is updated to point to a newly allocated *SimpleTerm* AST node (§916).

This method should probably be moved closer to the other methods used when parsing terms.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.ProcessSimpleTerm;
  begin gLastTerm ← new(SimpleTermPtr, Init(CurPos, GetIdentifier));
  end;
```

1581. Qualified terms. The Parser invokes *ProcessQua* when it is looking directly at a “qua” token, specifically in the *AppendQua* (§1689) procedure. The *ProcessQua* method is used nowhere else. It is solely responsible for “marking the current position” of the Parser, and storing that in the caller's *nQuaPos* field.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.ProcessQua;
  begin nQuaPos ← CurPos
  end;
```

1582. The Parser invokes the *FinishedQualifiedTerm* method after encountering a “qua” and after parsing the type. This method constructs a new *QualifiedTerm* object reflecting the top of the *Term* stack is taken “qua” the *gLastType*, and the mutates the top of the *Term* stack to be this newly allocated *QualifiedTerm* object.

This method does not push anything new to the term stack, but it does mutate the *Term* stack.

This method is used nowhere else other than the Parser's *AppendQua* (§1689) procedure.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.FinishQualifiedTerm;
  begin Term[TermNbr] ← new(QualifiedTermPtr, Init(nQuaPos, Term[TermNbr], gLastType));
  end;
```

1583. Although the “**exactly**” reserved keyword is not used for anything, the method for *ProcessExactly* marks the current position and stores it in the caller's *nQuaPos*, then *updates* (**not** pushes) to the top of the term stack by turning the top of the stack into an *ExactlyTerm* object.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.ProcessExactly;
  begin nQuaPos ← CurPos; Term[TermNbr] ← new(ExactlyTermPtr, Init(nQuaPos, Term[TermNbr]));
  end;
```

1584. Arguments to a term. The *CheckTermLimit* procedure is a “private helper function” for the *FinishArgument* method.

⟨Extended subexpression implementation 1570⟩ +≡

```

procedure CheckTermLimit;
  var l: integer;
  begin if TermNbr ≥ length(Term) then
    begin l ← 2 * length(Term); setlength(Term, l);
    end;
  end;

```

1585. Pushing the Term stack. This method pushes the *gLastTerm* state variable’s contents to the *Term* stack, mutating the *TermNbr* and *Term* module-local variables.

⟨Extended subexpression implementation 1570⟩ +≡

```

procedure extSubexpObj.FinishArgument;
  begin CheckTermLimit; inc(TermNbr); Term[TermNbr] ← gLastTerm;
  end;

```

1586. Pop the Term stack. The evil twin to “pushing” an element onto a stack, “popping” a stack removes the top element. We pop the *Term* stack whenever we finish the term.

This is only used in *AppendFunc* (§1714).

This should probably check that the *Term* stack is not empty before being invoked.

⟨Extended subexpression implementation 1570⟩ +≡

```

procedure extSubexpObj.FinishTerm;
  begin gLastTerm ← Term[TermNbr]; dec(TermNbr);
  end;

```

Subsection 23.3.1. Parsing Types

1587. When we start parsing a new type, we make sure the *gLastType* state variable is not caching an old type. We assign it to be the **nil** pointer.

⟨Extended subexpression implementation 1570⟩ +≡

```

procedure extSubexpObj.StartType;
  begin gLastType ← nil;
  end;

```

1588. This is invoked only by the Parser’s *RadixTypeSubexpression* (§1727) procedure. The Parser delegates the work of storing the mode information to this method. In turn, the caller’s *nModeKind* field stores the current word’s token *Kind*, and the caller’s *nModeNr* field stores the current word’s number. The Parser’s current position is marked and stored in the caller’s *nSubexpPos* field.

But no state variables are mutated by this method.

⟨Extended subexpression implementation 1570⟩ +≡

```

procedure extSubexpObj.ProcessModeSymbol;
  begin nModeKind ← CurWord.Kind; nModeNr ← CurWord.Nr;
  if (CurWord.Kind = sy_Set) { ?^(AheadWord.Kind ≠ sy_Of)? }
  then nModeKind ← ModeSymbol; nSubexpPos ← CurPos;
  end ;

```

1589. The Parser has just finished parsing a type and its arguments — “ $\langle Mode \rangle$ of $\langle Term\text{-}list \rangle$ ” or “ $\langle Structure \rangle$ over $\langle Term\text{-}list \rangle$ ”. The data has been accumulated into the caller, which will now be constructed into an AST object. The newly allocated AST node will be stored in the *gLastType* state variable.

If the caller is trying to construct a mode which does not match the format recorded in the *gFormatsColl*, a 151 error will be raised.

Similarly, if the caller is trying to construct a structure which does not match the format recorded in the *gFormatsColl*, a 185 error will be raised.

This is invoked only by the Parser’s *RadixTypeSubexpression* (§1727) procedure.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.FinishType;
  var lFormatNr: integer;
  begin case nModeKind of
    ModeSymbol: begin
      lFormatNr  $\leftarrow$  gFormatsColl.LookUp_PrefixFormat(‘M’, nModeNr, TermNbr – nTermBase);
      if lFormatNr = 0 then Error(nSubexpPos, 151); { format missing }
      gLastType  $\leftarrow$  new(StandardTypePtr, Init(nSubexpPos, nModeNr, CreateArgs(nTermBase + 1)));
      end;
    StructureSymbol: begin
      lFormatNr  $\leftarrow$  gFormatsColl.LookUp_PrefixFormat(‘L’, nModeNr, TermNbr – nTermBase);
      if lFormatNr = 0 then SemErr(185); { format missing }
      gLastType  $\leftarrow$  new(StructTypePtr, Init(nSubexpPos, nModeNr, CreateArgs(nTermBase + 1)));
      end;
    othercases begin gLastType  $\leftarrow$  new(IncorrectTypePtr, Init(CurPos)); end;
  endcases;
end;
```

1590. If the Parser has the misfortune of trying to make sense of a malformed type expression, then with a heavy heart it invokes this method to update the *gLastType* state variable to be an incorrect type expression at the current position.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.InsertIncorrType;
  begin gLastType  $\leftarrow$  new(IncorrectTypePtr, Init(CurPos));
  end;
```

1591. When the Parser encounters a qualifying formula (“ $\langle Term \rangle$ is $\langle Type \rangle$ ”) or is parsing a type for a cluster (the “**cluster** ... **for** $\langle Type \rangle$ ”), after parsing the type, this method is invoked to **update** the *gLastType* state variable to store the *ClusteredType* AST node (which decorates a type — the contents of *gLastType* at the time of calling — with a bunch of attributes).

The caller’s *nAttrCollection* is transferred to the *gLastType*. At the end of the method, the caller’s *nAttrCollection* (array of pointers) is freed. This does not free the objects referenced by the pointers, however.

If *gLastType* = **nil**, then the Parser has somehow failed to parse the type expression. An error should be raised.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.CompleteType*;

var *j*: integer;

begin mizassert(5433, *gLastType* ≠ **nil**);

if *nAttrCollection.Count* > 0 **then**

begin *gLastType* ← new(*ClusteredTypePtr*, Init(*gLastType*↑.*nTypePos*, new(*PList*,
 Init(*nAttrCollection.Count*)), *gLastType*));

for *j* ← 0 **to** *nAttrCollection.Count* − 1 **do**

ClusteredTypePtr(*gLastType*↑.*nAdjectiveCluster*↑.Insert(*PObject*(*nAttrCollection.Items*↑[*j*]));

nAttrCollection.DeleteAll;

end;

end;

Subsection 23.3.2. Parsing operator precedence

1592. Mario Carneiro’s “Mizar in Rust” (§6.2) gives an overview of this parsing routine (see also his `mizar-rs/src/parser/miz.rs` for the Rust version of the same code). It is a constrained optimization problem. We shall take care to dissect this routine. This appears to be where operator precedence, the *gPriority* (§808) global variable, comes into play.

1593. Starting a “long term”.

We can observe that *nTermBase* is initialized upon construction to *TermNbr*; in *ProcessAtomicFormula* and *StartPrivateFormula* it is assigned to *TermNbr*.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.StartLongTerm*;

begin *nArgListNbr* ← 0; *nArgList*[0].Length ← *TermNbr* − *nTermBase*;

end;

1594. Malformed term errors.

We should remind the reader, errors 165–175 are “unknown functor format”, errors 176 is “unknown attribute format”, and error 177 is “unknown structure format”. Only when such an error occurs, the flow experiences a **goto** *AfterBalance*.

For an example of a 168, 169 error:

```
for x being Nat
holds (id + x +) = x;
```

For an example of a 170, 171 error (the first 0 will be flagged 170, the second 0 will be flagged as 171):

```
for x being Nat
holds 0 0 + x = x;
```

For an example of a 172, 173 error:

```
for x being Nat
holds x + / = x;
```

For an example of a 174, 175 error:

```
for x being Nat
holds x + (1,2) + x = x;
```

1595. We can recall that a “generic” term looks like an infix operator of the form

$$(t_1^{(\ell)}, \dots, t_m^{(\ell)}) t (t_1^{(r)}, \dots, t_n^{(r)})$$

The parentheses are optional. Constants will have $m = n = 0$ and look like $() t ()$. Function-like terms will have $m = 0$ and look like $() t (t_1^{(r)}, \dots, t_n^{(r)})$. The problem statement could be re-phrased as: given several infix terms without parentheses inserted anywhere, determine how to cluster terms together.

1596. The problem statement for constructing the syntax tree for a term is something like the following: we have an expression of the form

$$x_1^{(0)}, \dots, x_{k_0}^{(0)} F_1 x_1^{(1)}, \dots, x_{k_1}^{(1)} F_2 \cdots F_n x_1^{(n)}, \dots, x_{k_n}^{(n)}$$

We want to produce a suitable binary tree with F_i on the internal nodes and the $(x_j^{(i)})_{j \leq k_i}$ on the leafs, respecting precedence such that each F_i is applied to the correct number of arguments.

Mario Carneiro noted ([arXiv:2304.08391](https://arxiv.org/abs/2304.08391), §6.2) the existence of an $O(n^4)$ algorithm using dynamic programming techniques. The trick is to compute the minimal “cost” [number of violations] for each substring of nodes $F_a \cdots F_b$ for each $1 \leq a \leq i \leq b \leq n$ with node F_i being the root of the subtree. There are $O(n^3)$ such subproblems, and they can be calculated from smaller subproblems in $O(n)$. This might seem alarmingly large, but usually the terms in Mizar are sufficiently small.

It is interesting to see how other languages tackle this problem, so I am going to give a haphazard literature review:

- (1) Nils Anders Danielsson and Ulf Norell’s “Parsing Mixfix Operators” (in SB. Scholz and O. Chitil (eds.), *Symposium on Implementation and Application of Functional Languages*, Springer 2008, pp. 80–99; [doi:10.1007/978-3-642-24452-0_5](https://doi.org/10.1007/978-3-642-24452-0_5)) discuss how Agda approaches parsing mixfix operators with different precedence.
- (2) The Isabelle proof assistant uses a modified version of Earley parsing of terms, supporting precedence between 0 to 1000.

1597. The only two place where *FinishLongTerm* is invoked is in the *AppendFunc* procedure (§1714) in *parser.pas*.

This relies on *MFormatsList.LookUpFuncFormat* (§827), which attempts to look up an *MinfixFormatObj* (§815) with a given id number as well as number of left and right arguments.

We will need to populate *ArgsLength* and *To_Right* to determine the syntax tree for the term (which is our real goal here). The *ArgsLength* encodes the number of terms are to the left and right of each “internal node”. The *To_Right* controls associativity (which is how Mizar handles operator precedence): if node F_{k+1} is higher precedence than node F_k , then *To_Right*(k) is true.

The *Exchange*(i) procedure will make node i a child of $i-1$ (when node i is a child of $i-1$), and vice-versa. Visually, this means we transform the tree as:

$$(\cdots F_{i-1} x_1, \dots, x_\ell), x_{\ell+1}, \dots, x_n F_i \cdots \longleftrightarrow \cdots F_{i-1} x_1, \dots, x_{\ell-1}, (x_\ell, x_{\ell+1}, \dots, x_n F_i \cdots)$$

Observe that “*Exchange*(i); *Exchange*(i)” is equivalent to doing nothing.

We should recall (§1567) that *nArgList* is an array of “**record** *Instance*, *SymPri*: *integer*; *FuncPos*: *Position*; **end**”.

⟨Extended subexpression implementation 1570⟩ $\vdash \equiv$

procedure *extSubexpObj.FinishLongTerm*;

var *ArgsLength*: **array of record** l, r : *integer*;

end;

To_Right: **array of** *boolean*;

1601. We first allocate the arrays, then we initialize the values.

```

⟨ Initialize To_Right and ArgsLength arrays 1601 ⟩  $\equiv$ 
  setlength(ArgsLength,  $nArgListNbr + 1$ ); setlength(To_Right,  $nArgListNbr + 1$ );
  setlength(Depo,  $nArgListNbr + 1$ );

```

See also section 1602.

This code is used in section 1598.

1602. The initial guess depends on whether F_k has precedence over F_{k+1} or not.

If F_{k+1} has higher precedence than F_k , then the initial guess groups terms as:

$$\cdots F_k ((x_1^{(k)}, \dots, x_{m_k}^{(k)}) F_{k+1}(\cdots)) \cdots, \quad \text{and} \quad To_Right[k] = true.$$

On the other hand, if F_{k+1} *does not* have higher precedence than F_k , then we guess the terms are grouped as

$$\cdots (\cdots F_k(x_1^{(k)}, \dots, x_{m_k}^{(k)}) F_{k+1} \cdots), \quad \text{and} \quad To_Right[k] = false.$$

This is a first stab, but sometimes we get lucky and it's correct.

define *next_term_has_higher_precedence*(#) \equiv
 $gPriority.Value(ord(\text{`0`}), nFunc[\#].Instance) < gPriority.Value(ord(\text{`0`}), nFunc[\# + 1].Instance)$

(Initialize *To_Right* and *ArgsLength* arrays 1601) \equiv

```

  ArgsLength[1].l  $\leftarrow$  nArgList[0].Length; To_Right[0]  $\leftarrow$  true;
  for k  $\leftarrow$  1 to nArgListNbr - 1 do
    with ArgsLength[k] do
      if next_term_has_higher_precedence(k) then
        begin r  $\leftarrow$  1; ArgsLength[k + 1].l  $\leftarrow$  nArgList[k].Length; To_Right[k]  $\leftarrow$  true end
      else begin r  $\leftarrow$  nArgList[k].Length; ArgsLength[k + 1].l  $\leftarrow$  1; To_Right[k]  $\leftarrow$  false end;
  ArgsLength[nArgListNbr].r  $\leftarrow$  nArgList[nArgListNbr].Length; To_Right[nArgListNbr]  $\leftarrow$  false;
```

1603. The first situation we encounter is if the user tries to tell Mizar to evaluate something like:

```

for x being Nat
holds x + (1,2) = x;
```

Mizar will not understand “ $x + (1,2)$ ” because it is an invalid functor format — the format would look something like $\langle +, \text{left} : 1, \text{right} : 1 \rangle$ but the format of the expression is $\langle \text{left} : 1, \text{right} : 2 \rangle$. The mismatch on the “right” values in the formats will raise a 165 error.

For a 166 error example,

```

for x being Nat
holds + / = x;
```

Mizar will not like the leading “+ /” expression, and flag this with the 166 error.

Mizar will flag “+ 0” as a 165 error.

(Initialize *Bl*, **goto** *AfterBalance* if term has at most one argument 1603) \equiv

```

Subsection 23.3.3. Processing subexpressions

1609. Note that *ProcessFunctorSymbol* is the only place where *nArgListNbr* is incremented. Processing functor symbols occurs in the Parser’s *AppendFunc* (§1714) in a loop.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.ProcessFunctorSymbol;
  var l: integer;
  begin inc(nArgListNbr);
  if nArgListNbr ≥ length(nFunc) then
    begin l ← 2 * length(nFunc) + 1; setlength(nArgList, l); setlength(nFunc, l);
    end;
  nArgList[nArgListNbr].Start ← TermNbr + 1; nFunc[nArgListNbr].FuncPos ← CurPos;
  nFunc[nArgListNbr].Instance ← CurWord.Nr;
  end;
```

1610. The Parser is in the middle of *AppendFunc* and has just finished parsing a term *t* or a tuple of terms (*t*₁, . . . , *t*_{*n*}). Before the Parser checks if it’s looking at an infix functor operator or not, the Parser invokes the *FinishArgList* method. It’s the only time where the *FinishArgList* method is invoked.

This allocates either 1 or *n* to the length of *nArgList*[*nArgListNbr*], to store the information for the term(s).

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.FinishArgList;
  begin nArgList[nArgListNbr].Length ← TermNbr − nArgList[nArgListNbr].Start + 1;
  end;
```

1611. The Parser is looking at “where” or (when the variables are all reserved) a colon “:”, the Parser invokes the *StartFraenkelTerm* which will store the previous term in the *nSample* field — so schematically, the Fraenkel term could look like

$$\{\langle nSample \rangle \textbf{ where } \langle Postqualification \rangle : \langle Formula \rangle\}$$

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.StartFraenkelTerm;
  begin nSample ← gLastTerm;
  end;
```

1612. This is only invoked in the Parser’s *ProcessPostqualification* (§1691) procedure, which is only invoked after the Parser calls the *extSubexp* object’s *StartFraenkelTerm* method.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.StartPostqualification;
  begin nPostQualList.Init(0);
  end;
```

1613. The Parser is looking at the post-qualified segment of a Fraenkel operator. This will be a list of variables “being” a type, we allocate an array for the variables. This is handled by the *StartPostQualifyingSegment* method.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.StartPostQualifyingSegment;
  begin nSegmentIdentColl.Init(2);
  end;
```

1614. While looping over the comma-separated list of variables in a post-qualified segment (in a Fraenkel term), the Parser invokes the *ProcessPostqualifiedVariable* on each iteration until it has parsed all the variables. This allocates a new *Variable* object, and pushes it onto the *nSegmentIdentColl* “stack”.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.ProcessPostqualifiedVariable;
  begin nSegmentIdentColl.Insert(new(VariablePtr, Init(CurPos, GetIdentifier)));
  end;
```

1615. The Parser is looking at “is” or “are” in a Fraenkel term’s post-qualification segment, but has not yet parsed the type. This method will assign the *nSegmentPos* field to be the current position, and assign the *gLastType* state variable to be the **nil** pointer.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.StartPostqualificationSpecyfication;
  begin nSegmentPos ← CurPos; gLastType ← nil;
  end;
```

1616. The Parser has just parsed either (1) a comma-separated list of variables, the copula “is” or “are”, and the type; or (2) a comma-separated list of reserved variables (but no copula and no type). We just need to construct an appropriate node for the abstract syntax tree. This method will append a new Segment to the *nPostQualList*.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.FinishPostQualifyingSegment;
  var k: integer; lSegment: ExplicitlyQualifiedSegmentPtr;
  begin if gLastType ≠ nil then
    begin lSegment ← new(ExplicitlyQualifiedSegmentPtr, Init(nSegmentPos, new(PList, Init(0)),
      gLastType)); nPostQualList.Insert(lSegment);
    for k ← 0 to nSegmentIdentColl.Count − 1 do
      begin ExplicitlyQualifiedSegmentPtr(lSegment)↑.nIdentifiers.Insert(nSegmentIdentColl.Items↑[k]);
      end;
    end
  else begin for k ← 0 to nSegmentIdentColl.Count − 1 do
    begin nPostQualList.Insert(new(ImplicitlyQualifiedSegmentPtr,
      Init(VariablePtr(nSegmentIdentColl.Items↑[k])↑.nVarPos, nSegmentIdentColl.Items↑[k])));
    end;
  end;
  nSegmentIdentColl.DeleteAll; nSegmentIdentColl.Done;
end;
```

1617. The Parser has just finished the formula in a Fraenkel term, and it is staring at the closet “}” bracket. The Parser invokes this method to construct a new *FraenkelTerm* AST node, and updates the *gLastTerm* to point at it.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.FinishFraenkelTerm;
  begin gLastTerm ← new(FraenkelTermPtr, Init(CurPos, new(PList, MoveList(nPostQualList)),
    nSample, gLastFormula));
  end;
```

1618. The Parser has already encountered “**the set**” and the next token is “**of**”, which means the Parser has encountered a “simple” Fraenkel term of the form “**the set of all** $\langle Term \rangle \dots$ ”. This method will be invoked once the Parser has stumbled across the “**all**”. The caller updates its $nAllPos$ to the Parser’s current position.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$
procedure *extSubexpObj.StartSimpleFraenkelTerm*;
 begin $nAllPos \leftarrow CurPos$;
 end;

1619. The Parser has just finished parsing the post-qualification to the simple Fraenkel term, which means it has finished parsing the simple Fraenkel term. This method allocates a new *SimpleFraenkelTerm* AST node with the accumulated AST nodes, then updates the $gLastTerm$ to point to the allocated *SimpleFraenkelTerm* node.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$
procedure *extSubexpObj.FinishSimpleFraenkelTerm*;
 begin $gLastTerm \leftarrow new(SimpleFraenkelTermPtr, Init(nAllPos, new(PList, MoveList(nPostQualList)), nSample))$;
 end;

1620. The Parser is looking at a closed term of the form “ $\langle Identifier \rangle (\dots$ ”, and so it looks like a private functor. This method updates the caller’s $nSubexpPos$ to the Parser’s current position, and the $nSpelling$ is assigned to the identifier’s number (for the private functor).

\langle Extended subexpression implementation 1570 $\rangle + \equiv$
procedure *extSubexpObj.StartPrivateTerm*;
 begin $nSubexpPos \leftarrow CurPos$; $nSpelling \leftarrow CurWord.Nr$;
 end;

1621. The Parser just finished parsing all the arguments to the private functor, and is looking at the closing parentheses for the private functor. This method allocates a new *PrivateFunctorTerm* object, using the arguments just parsed, and updates the $gLastTerm$ state variable to point to it.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$
procedure *extSubexpObj.FinishPrivateTerm*;
 begin $gLastTerm \leftarrow new(PrivateFunctorTermPtr, Init(nSubexpPos, nSpelling, CreateArgs(nTermBase + 1)))$;
 end;

1622. The Parser has just encountered either a left bracket term or the opening left bracket for a set “{”. The Parser calls this method, which just updates the caller’s $nSymbolNr$ to be whatever the current token’s numeric ID value is.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$
procedure *extSubexpObj.StartBracketedTerm*;
 begin $nSymbolNr \leftarrow CurWord.Nr$;
 end;

1623. If the Parser is in panic mode, this method does nothing.

Either the Parser has finished parsing an enumerated set $\{x_1, \dots, x_n\}$ or a bracketed term. We need to double check the format for the bracket matches what is stored in the *gFormatsColl*, and raise a 152 error if there's a mismatch. Otherwise, allocate a new AST node for the bracketed term, and use *CreateArgs* on the terms contained within the brackets.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.FinishBracketedTerm*;

var *lFormatNr*: integer;

begin if *StillCorrect* **then**

begin *nRSymbolNr* \leftarrow *CurWord.Nr*; *lFormatNr* \leftarrow *gFormatsColl.LookUp_BracketFormat*(*nSymbolNr*,
 nRSymbolNr, *TermNbr* - *nTermBase*, 0, 0);

if *lFormatNr* = 0 **then** *SemErr*(152);

gLastTerm \leftarrow *new*(*CircumfixTermPtr*, *Init*(*CurPos*, *nSymbolNr*, *nRSymbolNr*,
 CreateArgs(*nTermBase* + 1)));

end;

end;

1624. Remember that Mizar calls “an instance of structure” an “**Aggregate**”. When the Parser is parsing for a closed subterm and has stumbled across a structure constructor (§1698), it first invokes this method. This stores the ID number for the structure in the caller's *nSymbolNr*.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.StartAggregateTerm*;

begin *nSymbolNr* \leftarrow *CurWord.Nr*;

end;

1625. The Parser has just parsed the arguments for the structure constructor, and the Parser is now looking at the “#” token. This method is invoked.

We should check the format for the structure constructor is stored in the *gFormatsColl*. If not, raise a 176 error. Otherwise, we allocate a new *AggregateTerm* with the parsed arguments, and then update the *gLastTerm* pointer to point at it.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.FinishAggregateTerm*;

var *lFormatNr*: integer;

begin *lFormatNr* \leftarrow *gFormatsColl.LookUp_PrefixFormat*(“G”, *nSymbolNr*, *TermNbr* - *nTermBase*);

if *lFormatNr* = 0 **then** *Error*(*CurPos*, 176); { missing format error }

gLastTerm \leftarrow *new*(*AggregateTermPtr*, *Init*(*CurPos*, *nSymbolNr*, *CreateArgs*(*nTermBase* + 1)));

end;

1626. The Parser is parsing for a closed subterm, and has stumbled across “the” and is looking at a selector token (§1706). This method is invoked. We assign the caller's *nSymbolNr* to the ID number for the selector token, assign the caller's *nSubexpPos* to the Parser's current position, and store the next token's kind (i.e., the “of” token's kind) in the *nNextWord* field.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.StartSelectorTerm*;

begin *nSymbolNr* \leftarrow *CurWord.Nr*; *nSubexpPos* \leftarrow *CurPos*; *nNextWord* \leftarrow *AheadWord.Kind*;

end;

1627. The Parser has just parsed “the $\langle Selector \rangle$ of $\langle Term \rangle$ ”. Now this method is invoked to assemble the parsed data into an AST node.

If there is no selector with this matching format, then a 182 error will be raised.

If the caller’s *nNextWord* is an “of” token’s kind, then we’re describing a selector term. We update the *gLastTerm* state variable to point to a newly allocated *SelectorTerm* object with the appropriate data set.

On the other hand, “**internal selectors**” occur when defining a structure. For example,

```
struct (1-sorted) multMagma (#
  carrier -> set,
  multF -> BinOp of the carrier
#);
```

Observe the *multF* specification is *BinOp of the carrier*. That “the carrier” is an internal selector. In this case, allocate a new *InternalSelectorTerm* object, and update the *gLastTerm* state variable to point to it.

If, for some reason, the Parser is in neither situation, then just *gLastTerm* state variable to be an incorrect term.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```
procedure extSubexpObj.FinishSelectorTerm;
  var lFormatNr: integer;
  begin lFormatNr ← gFormatsColl.LookUp_PrefixFormat(‘U’, nSymbolNr, 1);
  if lFormatNr = 0 then Error(nSubexpPos, 182); { missing format error }
  if nNextWord = sy_Of then
    gLastTerm ← new(SelectorTermPtr, Init(nSubexpPos, nSymbolNr, gLastTerm))
  else if in_AggrPattern then
    gLastTerm ← new(InternalSelectorTermPtr, Init(nSubexpPos, nSymbolNr))
  else begin gLastTerm ← new(IncorrectTermPtr, Init(nSubexpPos)); Error(nSubexpPos, 329)
    end;
  end;
```

1628. The Parser is about to start parsing a forgetful functor (§1709) — for example “the *multMagma* of *REAL.TopGroup*”. This method is invoked. The caller’s *nSymbolNr* field is updated to the current token’s ID Number, the *nSubexpPos* field is assigned the Parser’s current position, and the *nNextWord* field is assigned to the token kind of the next token — this is expected to be “of”.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```
procedure extSubexpObj.StartForgetfulTerm;
  begin nSymbolNr ← CurWord.Nr; nSubexpPos ← CurPos; nNextWord ← AheadWord.Kind;
  end;
```

1629. The Parser just finished parsing a forgetful functor. If the Parser is not panicking, check the format for the forgetful functor matches what is stored in the *gFormatsColl* state variable. If the format is invalid, raise a 184 error.

Whether the Parser is panicking or not, allocate a new *ForgetfulFunctor* term, and update the *gLastTerm* to point to it.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.FinishForgetfulTerm*;

var *lFormatNr*: integer;

begin *lFormatNr* ← 0;

if *StillCorrect* **then**

begin *lFormatNr* ← *gFormatsColl.LookUp_PrefixFormat*(*ˆJ*, *nSymbolNr*, 1);

if *lFormatNr* = 0 **then** *Error*(*nSubexpPos*, 184); { missing format }

end;

gLastTerm ← *new*(*ForgetfulFunctorTermPtr*, *Init*(*nSubexpPos*, *nSymbolNr*, *gLastTerm*));

end;

1630. There are several situations where this is invoked:

- (1) The Parser has just parsed “the” but is not looking at a selector symbol (“the multF of...”), nor is the Parser looking at a forgetful functor (“the multMagma of...”). Then this is interpreted as looking at a choice operator (§1706).
- (2) The Parser has just parsed “the” but is not looking at a forgetful functor, so the Parser believes it must be looking at a choice operator (§1709).
- (3) The Parser has just parsed “the” and is now looking at “set” — so this is invoking the axiom of choice to pick “the set” (§1711).

In these three situations, the Parser invokes this method. It just updates the caller’s *nSubexpPos* field to point to the Parser’s current position.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.StartChoiceTerm*;

begin *nSubexpPos* ← *CurPos*;

end;

1631. The Parser has just parsed a type, and now believes it has finished parsing a choice expression. Then it invokes this method to construct an appropriate AST node for the term, by specifically allocating a new *ChoiceTerm* for the *gLastType* type. We then update the *gLastTerm* state variable to point to this newly allocated term.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.FinishChoiceTerm*;

begin *gLastTerm* ← *new*(*ChoiceTermPtr*, *Init*(*nSubexpPos*, *gLastType*));

end;

1632. When the Parser encounters a numeral while seeking a closed subterm (§1695), it invokes this method to allocate a new *NumeralTerm*. The *gLastTerm* state variable is updated to point to this newly allocated numeral object.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.ProcessNumeralTerm*;

begin *gLastTerm* ← *new*(*NumeralTermPtr*, *Init*(*CurPos*, *CurWord.Nr*));

end;

1633. The Parser tries to parse a closed subterm (§1695) and encounters the “it” token. Well, if the *it_Allowed* state variable is true, then we should allocate a new *ItTerm* and update the *gLastTerm* state variable to point to it.

Otherwise, when the *it_Allowed* state variable is false, we should raise a 251 error.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.ProcessItTerm;
  begin if it_Allowed then gLastTerm ← new(ItTermPtr, Init(CurPos))
  else begin gLastTerm ← new(IncorrectTermPtr, Init(CurPos)); ErrImm(251)
    end;
  end;
```

1634. The Parser tries parsing for a closed subterm and has encountered a placeholder term for a private functor (e.g., “\$1”). If the *dol_Allowed* state variable is true, then allocate a new *PlaceholderTerm* object and update the *gLastTerm* state variable to point at it.

If the *dol_Allowed* state variable is false, then we should raise a 181 error.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.ProcessLocusTerm;
  begin if dol_Allowed then gLastTerm ← new(PlaceholderTermPtr, Init(CurPos, CurWord.Nr))
  else begin gLastTerm ← new(IncorrectTermPtr, Init(CurPos)); ErrImm(181)
    end;
  end;
```

1635. Calamity! An incorrect expression has crossed the Parser’s path. Allocate an *IncorrectTerm* object located at the Parser’s current position, then update the *gLastTerm* state variable to point to it.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.InsertIncorrTerm;
  begin gLastTerm ← new(IncorrectTermPtr, Init(CurPos));
  end;
```

Subsection 23.3.4. Parsing formulas

1636. The Parser is trying to parse an atomic formula (§1752), but something has gone awry. Allocate a new *IncorrectFormula* object located at the Parser’s current position, update the *gLastFormula* state variable to point to it, and “reset” the *TermNbr* state variable to point to where the caller’s *nTermBase* is located.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.InsertIncorrBasic;
  begin gLastFormula ← new(IncorrectFormulaPtr, Init(CurPos)); TermNbr ← nTermBase;
  end;
```

1637. While the Parser was trying to parse a formula, it found something which “doesn’t quite fit”. Allocate a new *IncorrectFormula* object, then update the *gLastFormula* state variable to point to it.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.InsertIncorrFormula;
  begin gLastFormula ← new(IncorrectFormulaPtr, Init(CurPos));
  end;
```

1638. If we are in a proof, allocate a new *ThesisFormula* object (recall the `WEB` macro for this §1399). Otherwise, raise a 65 error.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.ProcessThesis;
  begin if gProofCnt > 0 then gLastFormula ← thesis_formula
  else begin ErrImm(65); gLastFormula ← new(IncorrectFormulaPtr, Init(CurPos));
    end;
  end;
```

1639. The Parser has encountered “⟨*Term*⟩ **is**”, or some other generic atomic formula (§1752), this method is invoked.

If more than one term appears before the “**is**” token (i.e., if $TermNbr - nTermBase \neq 1$), then a 157 error is raised. There is a Polish comment here, “Trzeba chyba wstawic recovery dla $TermNbr = nTermBase$ ”, which I translated to English.

This will initialize the fields for the caller in preparation for parsing some atomic formula. In particular, this is the only place where *TermNbr* is initialized to a nonzero value (and isn’t in an incorrect formula).

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.ProcessAtomicFormula;
  const MaxArgListNbr = 20;
  begin nSubexpPos ← CurPos; nSymbolNr ← 0;
  case CurWord.Kind of
    sy_Is: if  $TermNbr - nTermBase \neq 1$  then
      begin ErrImm(157); TermNbr ← nTermBase; InsertIncorrTerm; FinishArgument;
        { I think you need to insert recovery for  $TermNbr = nTermBase$  }
      end;
    endcases;
  nRightArgBase ← TermNbr; nTermBase ← TermNbr; nPostNegated ← false; nArgListNbr ← 0;
  nArgList[0].Start ← TermNbr + 1;
  end;
```

1640. The Parser is either finishing a “predicative formula” (§1751) or it’s parsing a predicate pattern (§1853), it invokes this method to initialize the fields needed when forming an AST node. Specifically, the *nSubexpPos* is assigned to the Parser’s current position, the *nSymbolNr* is updated either to the current token’s ID number (if the current token is “=” or a predicate) or else assigned to be zero. Last, the *nRightArgBase* is assigned to equal the *TermNbr* state variable.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.ProcessPredicateSymbol;
  begin nSubexpPos ← CurPos;
  case CurWord.Kind of
    sy_Equal, PredicateSymbol: nSymbolNr ← CurWord.Nr;
  othercases nSymbolNr ← 0;
  endcases;
  nRightArgBase ← TermNbr;
  end;
```

1641. The Parser is parsing a “predicate formula” which has arguments on the righthand side of the predicate symbol (§1746).

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.ProcessRightSideOfPredicateSymbol;
  begin nRightSideOfPredPos ← CurPos;
  case CurWord.Kind of
    sy_Equal, PredicateSymbol: nSymbolNr ← CurWord.Nr;
  othercases nSymbolNr ← 0;
  endcases;
  nRightArgBase ← TermNbr;
end;
```

1642. The Parser has just finished a “predicate formula” (§1751), then this method is invoked to construct an AST for the formula. First we check if the format is valid. If the format for the formula is not found in the *gFormatsColl*, then we must raise a 153 error. Otherwise, we construct two lists (one for the left arguments, another for the right arguments), and use them to construct a new *PredicativeFormula* object. We update the *gLastFormula* state variable to point to the newly allocated formula object.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.FinishPredicativeFormula;
  var lLeftArgs, lRightArgs: PList; lFormatNr: integer;
  begin lFormatNr ← gFormatsColl.LookUp_PredFormat(nSymbolNr, nRightArgBase − nTermBase,
    TermNbr − nRightArgBase);
  if lFormatNr = 0 then Error(nSubexpPos, 153); { missing format }
  lRightArgs ← CreateArgs(nRightArgBase + 1); lLeftArgs ← CreateArgs(nTermBase + 1);
  gLastFormula ← new(PredicativeFormulaPtr, Init(nSubexpPos, nSymbolNr, lLeftArgs, lRightArgs));
end;
```

1643. The Parser tries to construct an AST when finishing up the right-hand side of a predicative formula (§1746), it invokes this method after the *extSubexpObj.FinishPredicativeFormula* has been invoked.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.FinishRightSideOfPredicativeFormula;
  var lRightArgs: PList; lLeftArgsNbr, lFormatNr: integer; lFrm: FormulaPtr;
  begin lFrm ← gLastFormula;
  if lFrm.nFormulaSort = wsNegatedFormula then lFrm ← NegativeFormulaPtr(lFrm).nArg;
  lLeftArgsNbr ← RightSideOfPredicativeFormulaPtr(lFrm).nRightArgs.Count;
  lFormatNr ← gFormatsColl.LookUp_PredFormat(nSymbolNr, lLeftArgsNbr, TermNbr − nRightArgBase);
  if lFormatNr = 0 then Error(nSubexpPos, 153); { missing format }
  lRightArgs ← CreateArgs(nRightArgBase + 1);
  gLastFormula ← new(RightSideOfPredicativeFormulaPtr, Init(nSubexpPos, nSymbolNr, lRightArgs));
  nMultiPredicateList.Insert(gLastFormula);
end;
```

1644. When the Parser is parsing an atomic formula, when it has parsed a formula and encounters another predicate, it defaults to thinking that it is starting a “multi-predicative formula” (§1747), and it invokes this method. This initializes the *nMultiPredicateList* to an empty list of length 4, and the first entry points to the same formula pointed to by the *gLastFormula* state variable.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.StartMultiPredicativeFormula;
  begin nMultiPredicateList.Init(4); nMultiPredicateList.Insert(gLastFormula);
end;
```

1645. Finishing a “multi-predicative formula” allocates a new *MultiPredicativeFormula* object, and moves the contents of the caller’s *nMultiPredicateList* to the newly minted formula. The *gLastFormula* state variable is updated to point to this newly allocated formula object.

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.FinishMultiPredicativeFormula;
  begin gLastFormula ← new(MultiPredicativeFormulaPtr, Init(nSubexpPos, new(PList,
    MoveList(nMultiPredicateList))));
  end;
```

1646. The Parser has just parsed “⟨*Term*⟩ is ⟨*Type*⟩”, and now we need to store the accumulated data into a Formula AST. Of course, if the *gLastType* variable is not pointing to a type object, then we should raise an error (clearly something has gone wrong somewhere).

If we have accumulated attributes while parsing, then we should update the *gLastType* to be a clustered type object (and we should move the attributes over).

We should allocate a *QualifiedFormula* object, update the *gLastFormula* state variable to point to it. If the Parser has encountered “⟨*Term*⟩ is not ⟨*Type*⟩”, then it will tell the caller to toggle the *nPostNegated* to be true — and in that case, we should negate the *gLastFormula* state variable.

We mutate the *TermNbr* state variable, decrementing it by one (since we consumed the top of the term stack).

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.FinishQualifyingFormula;
  var j: integer;
  begin mizassert(5430, gLastType ≠ nil);
  if nAttrCollection.Count > 0 then
    begin gLastType ← new(ClusteredTypePtr, Init(gLastType↑.nTypePos, new(PList,
      Init(nAttrCollection.Count), gLastType)));
    for j ← 0 to nAttrCollection.Count − 1 do
      ClusteredTypePtr(gLastType↑).nAdjectiveCluster↑.Insert(PObject(nAttrCollection.Items↑[j]));
    end;
    gLastFormula ← new(QualifyingFormulaPtr, Init(nSubexpPos, Term[TermNbr], gLastType));
    if nPostNegated then gLastFormula ← new(NegativeFormulaPtr, Init(nNotPos, gLastFormula));
    dec(TermNbr);
  end;
```

1647. The Parser has just finished parsing “⟨*Term*⟩ is ⟨*Attribute*⟩” or “⟨*Term*⟩ is not ⟨*Attribute*⟩”, and so it invokes this method. We allocate a new *AttributiveFormula* object, and negate it if needed. We also decrement the *TermNbr* state variable (since we consumed one element of the term stack).

⟨Extended subexpression implementation 1570⟩ +≡

```
procedure extSubexpObj.FinishAttributiveFormula;
  begin gLastFormula ← new(AttributiveFormulaPtr, Init(nSubExpPos, Term[TermNbr], new(PList,
    MoveList(nAttrCollection))));
  if nPostNegated then gLastFormula ← new(NegativeFormulaPtr, Init(nNotPos, gLastFormula));
  dec(TermNbr);
  end;
```

1648. While the Parser is working its way through a formula, and it is looking at an identifier and the next token is a square bracket “[”, then the Parser invokes this method to initialize the relevant fields to store accumulated data.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.StartPrivateFormula*;

begin *nTermBase* \leftarrow *TermNbr*; *nSubexpPos* \leftarrow *CurPos*; *nSpelling* \leftarrow *CurWord.Nr*;
end;

1649. The Parser has just encountered “]” and now we assemble the accumulated data into a formula. This allocates a new *PrivatePredicativeFormula*, moves the arguments encountered since starting the private predicate into a list (§1573) owned by the formula object. The *gLastFormula* is updated to point to the newly allocated formula object.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.FinishPrivateFormula*;

begin *gLastFormula* \leftarrow *new(PrivatePredicativeFormulaPtr, Init(nSubexpPos, nSpelling, CreateArgs(nTermBase + 1)))*;
end;

1650. The Parser has encountered the “contradiction” token, so it invokes this method, which allocates a *ContradictionFormula* and updates the *gLastFormula* state variable to point to it.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.ProcessContradiction*;

begin *gLastFormula* \leftarrow *new(ContradictionFormulaPtr, Init(CurPos))*;
end;

1651. The Parser routinely allocates a formula object, then realizes later it should negate that formula object. This is handled by storing the formula object in the *gLastFormula* object, then this method allocates a new formula (which is the negation of the *gLastFormula*) and updates the *gLastFormula* to point to the newly allocated negated formula.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.ProcessNegation*;

begin *gLastFormula* \leftarrow *new(NegativeFormulaPtr, Init(CurPos, gLastFormula))*;
end;

1652. When the Parser has encountered the “not” reserved keyword, it invokes the *ProcessNegation* method which just toggles the *nPostNegated* field of the caller, and assigns the *nNotPos* field to the Parser’s current position.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.ProcessNegation*;

begin *nPostNegated* \leftarrow \neg *nPostNegated*; *nNotPos* \leftarrow *CurPos*;
end;

1653. When the Parser is looking at a binary connective token (e.g., “implies”, “or”, etc.), this method is invoked to store the connective kind as well as the “left-hand side” to the binary connective in the *nFirstSententialOperand* field.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.ProcessBinaryConnective*;

begin *nConnective* \leftarrow *CurWord.Kind*; *nFirstSententialOperand* \leftarrow *gLastFormula*;
nSubexpPos \leftarrow *CurPos*;
end;

```

 $\langle \text{Extended subexpression implementation } 1570 \rangle \equiv$ 
procedure extSubexpObj.ProcessFlexDisjunction;
begin nFirstSententialOperand  $\leftarrow$  gLastFormula;
end;

```

```

⟨Extended subexpression implementation 1570⟩ ≡
procedure extSubexpObj.ProcessFlexConjunction;
begin nFirstSententialOperand ← gLastFormula;
end;

```

```

 $\langle \text{Extended subexpression implementation } 1570 \rangle \equiv$ 
procedure extSubexpObj.StartRestriction;
begin nRestrPos  $\leftarrow$  CurPos;
end;

```

```

 $\langle \text{Extended subexpression implementation } 1570 \rangle + \equiv$ 
procedure extSubexpObj.FinishRestriction;
begin nRestriction  $\leftarrow$  gLastFormula;
end;

```

```

⟨Extended subexpression implementation 1570⟩ +≡
procedure extSubexpObj.FinishBinaryFormula;

```

```

begin case nConnective of
sy_Implies: gLastFormula  $\leftarrow$  new(ConditionalFormulaPtr, Init(nSubExpPos, nFirstSententialOperand,
gLastFormula));
sy_Iff: gLastFormula  $\leftarrow$  new(BiconditionalFormulaPtr, Init(nSubexpPos, nFirstSententialOperand,
gLastFormula));
sy_Or: gLastFormula  $\leftarrow$  new(DisjunctiveFormulaPtr, Init(nSubexpPos, nFirstSententialOperand,
gLastFormula));
sy_Ampersand: gLastFormula  $\leftarrow$  new(ConjunctiveFormulaPtr, Init(nSubexpPos,
nFirstSententialOperand, gLastFormula));
othercases RunTimeError(3124);
endcases;
end;

```

1659. We have parsed “ $\langle Formula \rangle$ or ... or $\langle Formula \rangle$ ”, and the Parser invokes this method to construct an AST for the formula. This method allocates a new *FlexaryDisjunctive* formula object, and updates the *gLastFormula* state variable to point to it.

There is a comment in Polish, “polaczyc z flexConj”, which Google translates to “connect to flexConj”.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```
procedure extSubexpObj.FinishFlexDisjunction; { polaczyc z flexConj }
begin gLastFormula  $\leftarrow$  new(FlexaryDisjunctiveFormulaPtr, Init(CurPos, nFirstSententialOperand,
    gLastFormula));
end;
```

1660. We have parsed “ $\langle Formula \rangle$ & ... & $\langle Formula \rangle$ ”, and the Parser invokes this method to construct an AST for the formula. This allocates a new *FlexaryConjunctive* formula object, and updates the *gLastFormula* state variable to point to it.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```
procedure extSubexpObj.FinishFlexConjunction;
begin gLastFormula  $\leftarrow$  new(FlexaryConjunctiveFormulaPtr, Init(CurPos, nFirstSententialOperand,
    gLastFormula));
end;
```

1661. The Parser is looking at the “ex” token, then invokes this method to reset the caller’s fields in preparation for accumulating data needed when constructing the formula’s AST.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```
procedure extSubexpObj.StartExistential;
begin nQualifiedSegments.Init(0); nSubexpPos  $\leftarrow$  CurPos;
end;
```

1662. The Parser is looking at the “for” token, and it invokes this method to reset the relevant fields in the caller.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```
procedure extSubexpObj.StartUniversal;
begin nQualifiedSegments.Init(0); nSubexpPos  $\leftarrow$  CurPos;
end;
```

1663. After the Parser has invoked *StartUniversal* or *StartExistential*, it parses the quantified variables (which begins by invoking this method).

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```
procedure extSubexpObj.StartQualifiedSegment;
begin nSegmentIdentColl.Init(2); nSegmentPos  $\leftarrow$  CurPos;
end;
```

1664. The Parser has parsed a comma-separated list and is expecting either “be” or “being”, but before parsing for that copula the Parser invokes the *StartQualifyingType* method to update the *gLastType* state variable to point to **nil**.

\langle Extended subexpression implementation 1570 $\rangle + \equiv$

```
procedure extSubexpObj.StartQualifyingType;
begin gLastType  $\leftarrow$  nil;
end;
```

1665. The Parser has just finished parsing quantified variables. There are two possible situations:

- (1) We have just parsed reserved variables, so the types are all known. Then the $gLastType = \mathbf{nil}$.
- (2) We have parsed an explicitly typed list of variables, so the $gLastType \neq \mathbf{nil}$.

In the first case, we should allocate an *ImplicitlyQualifiedSegment* object and move all the segment's identifiers to this object. Then we clean up the caller's $nSegmentIdentColl$ field (since it's an array of \mathbf{nil} pointers).

In the second case, we can just move the identifiers when allocating a new *ExplicitlyQualifiedSegment* object.

In both cases, the new allocated *QuantifiedSegment* object is appended to the caller's $nQualifiedSegments$ field.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.FinishQualifiedSegment*;

var k : integer;

begin if $gLastType = \mathbf{nil}$ **then**

begin for $k \leftarrow 0$ **to** $nSegmentIdentColl.Count - 1$ **do**

begin $nQualifiedSegments.Insert(new(ImplicitlyQualifiedSegmentPtr,$

$Init(VariablePtr(nSegmentIdentColl.Items↑[k])↑.nVarPos, nSegmentIdentColl.Items↑[k]));$

$nSegmentIdentColl.Items↑[k] \leftarrow \mathbf{nil}$;

end;

$nSegmentIdentColl.Done$;

end

else begin $nQualifiedSegments.Insert(new(ExplicitlyQualifiedSegmentPtr, Init(nSegmentPos,$
 $new(PList, MoveList(nSegmentIdentColl), gLastType)));$

end;

end;

1666. When the Parser is parsing quantified variables, specifically when it is parsing a comma-separated list of variables, it will invoke this method, then check if the next token is a comma (and if so iterate). This *ProcessVariable* method should accumulate a *Variable* object with the current token's identifier, then insert it into the caller's $nSegmentIdentColl$ field.

⟨Extended subexpression implementation 1570⟩ +≡

procedure *extSubexpObj.ProcessVariable*;

begin $nSegmentIdentColl.Insert(new(VariablePtr, Init(CurPos, GetIdentifier)));$

end;

1667. The Parser has just finished something like

$$\text{ex } \langle \text{Qualified-Variables} \rangle , \dots , \langle \text{Qualified-Variables} \rangle \text{ st } \langle \text{Formula} \rangle$$

Now we assemble it as

$$\text{ex } \langle \text{Qualified-Variables} \rangle \text{ st } (\text{ex } \dots \text{ st } (\text{ex } \langle \text{Qualified-Variables} \rangle \text{ st } \langle \text{Formula} \rangle))$$

starting with the innermost existentially quantified formula, working our ways outwards.

Importantly, assembling the AST reflects the quantified variables has the grammar

$$\begin{aligned} \langle \text{Qualified-Variables} \rangle &= \langle \text{Implicitly-Qualified-Variables} \rangle \\ &\quad | \langle \text{Explicitly-Qualified-Variables} \rangle \\ &\quad | \langle \text{Explicitly-Qualified-Variables} \rangle ", " \langle \text{Implicitly-Qualified-Variables} \rangle \end{aligned}$$

(Extended subexpression implementation 1570) +≡

procedure *extSubexpObj.FinishExistential*;

var *k*: integer;

begin for *k* ← *nQualifiedSegments.Count* − 1 **downto** 1 **do** { from inside outwards }

begin *gLastFormula* ← *new(ExistentialFormulaPtr, Init(QualifiedSegmentPtr(nQualifiedSegments.Items↑[k])↑.nSegmPos, nQualifiedSegments.Items↑[k], gLastFormula))*; *nQualifiedSegments.Items↑[k]* ← **nil**;

end;

if *nQualifiedSegments.Count* > 0 **then**

begin *gLastFormula* ← *new(ExistentialFormulaPtr, Init(nSubexpPos, nQualifiedSegments.Items↑[0], gLastFormula))*; *nQualifiedSegments.Items↑[0]* ← **nil**;

end;

nQualifiedSegments.Done;

end;

1668. Universally quantified formulas first transforms

$$\text{for } \langle \text{Qualified-Variables} \rangle \text{ st } \langle \text{Formula} \rangle_1 \text{ holds } \langle \text{Formula} \rangle_2$$

into

$$\text{for } \langle \text{Qualified-Variables} \rangle \text{ holds } \langle \text{Formula} \rangle_1 \text{ implies } \langle \text{Formula} \rangle_2$$

which is handled immediately.

The remainder of the method iteratively constructs the universally quantified formulas by “unrolling” the qualified segments, just as we did for existentially quantified formulas.

(Extended subexpression implementation 1570) +≡

procedure *extSubexpObj.FinishUniversal*;

var *k*: integer;

begin if *nRestriction* ≠ **nil** **then** { transform st into implies }

gLastFormula ← *new(ConditionalFormulaPtr, Init(nRestrPos, nRestriction, gLastFormula))*;

for *k* ← *nQualifiedSegments.Count* − 1 **downto** 1 **do**

begin *gLastFormula* ← *new(UniversalFormulaPtr, Init(QualifiedSegmentPtr(nQualifiedSegments.Items↑[k])↑.nSegmPos, nQualifiedSegments.Items↑[k], gLastFormula))*; *nQualifiedSegments.Items↑[k]* ← **nil**;

end;

if *nQualifiedSegments.Count* > 0 **then**

begin *gLastFormula* ← *new(UniversalFormulaPtr, Init(nSubexpPos, nQualifiedSegments.Items↑[0], gLastFormula))*; *nQualifiedSegments.Items↑[0]* ← **nil**;

end;

end;

Section 23.4. EXTENDED EXPRESSION CLASS

1669. When an expression is needed, the *gExpPtr* state variable is used to build it out of subexpressions. The *gExpPtr* state variable is an instance of the *extExpression* class.

⟨ Extended expression class declaration 1669 ⟩ ≡
extExpressionPtr = ↑*extExpressionObj*;
extExpressionObj = **object** (*ExpressionObj*)
constructor *Init* (*fExpKind* : *ExpKind*);
procedure *CreateSubexpression*; *virtual*;
end ;

This code is used in section 1379.

1670. Constructor. This just invokes the parent class's constructor (§871), then resets the module-wide variable *TermNbr* to zero.

⟨ Extended expression implementation 1670 ⟩ ≡
constructor *extExpressionObj.Init* (*fExpKind* : *ExpKind*);
begin *inherited Init* (*fExpKind*); *TermNbr* ← 0;
end;

See also section 1671.

This code is used in section 1380.

1671. An *extExpression* creating a subexpression *overrides* the parent class's method (§872), and sets the global *gSubexpPtr* to point to a new *extSubexp* object.

⟨ Extended expression implementation 1670 ⟩ +≡
procedure *extExpressionObj.CreateSubexpression*;
begin *gSubexpPtr* ← *new* (*extSubexpPtr*, *Init*)
end;

File 24

Parser

1672. The Parser has a “big red button”: a single “obvious” function for the user to, you know, push. Namely, the *Parse* procedure (§§1921 *et seq.*). Everything else is just a helper function.

The design of the Parser appears to be a recursive descent Parser on statements, with parsing expressions handled specially.

Note that the `base/parser.pas` file appears to be naturally divided up into sections, with comments which appear to use the Germanic “s p a c i n g f o r i t a l i c s” (which I have just replaced with more readable *italicized* versions). I have used these cleavages to organize the discussion of this file.

The *StillCorrect* global variable is *false* when the Parser has entered what programmers call “**Panic Mode**”: something has gone awry, and the Parser is trying to recover gracefully. For a friendly review of panicking, see Bob Nystrom’s *Crafting Interpreters* (Chapter 6, Section 3).

```

⟨ parser.pas 1672 ⟩ ≡
  ⟨ GNU License 4 ⟩
unit parser;
interface
  uses mscanner;
  var StillCorrect: boolean = true;
  type ReadTokenProcedure = Procedure;
  const ReadTokenProc: ReadTokenProcedure = ReadToken; { from mscanner.pas }
  procedure Parse;
  procedure SemErr(fErrNr : integer);
implementation
  uses syntax, errhan, pragmas
      mdebug, info end_mdebug;
  ⟨ Implementation of parser.pas 1673 ⟩

```

1673. We have a few constants, but the implementation is loosely organized around parsing expressions (terms and formulas), statements, and then blocks.

```

This code is used in section 1674.

1676. ⟨Implementation of parser.pas 1673⟩ +≡
var *gAddSymbolsSet*: **set of** *char* = []; { not used anywhere }

1677. Syntax errors do three things:

- (1) Marks *StillCorrect* to be false (i.e., enters panic mode)
- (2) Reports the error with the *ErrImm* (§130) function.
- (3) Skips ahead until we find a token in the *gMainSet*, then try to proceed like things are still alright (so we “fail gracefully”).

⟨Implementation of parser.pas 1673⟩ +≡
procedure *SynErr*(*fPos* : *Position*; *fErrNr* : *integer*);
begin if *StillCorrect* **then**
 begin *StillCorrect* ← *false*;
 if *CurWord.Kind* = *sy_Error* **then**
 begin if *CurWord.Nr* ≠ *scTooLongLineErrorNr* **then** *ErrImm*(*CurWord.Nr*)
 else *Error*(*fPos*, *fErrNr*);
 end
 else *Error*(*fPos*, *fErrNr*);
 while ¬(*CurWord.Kind* ∈ *gMainSet*) **do** *ReadTokenProc*;
 end;
end;

1678. What constants are good “check-in points” for the Parser to recover at? The beginning of blocks, the end of statements (especially semicolons), and the end of text.

Note: *gMainSet* is only used in the *SynErr* procedure, and nowhere else in Mizar.

⟨Local constants for parser.pas 1674⟩ +≡
const *gMainSet*: **set of** *TokenKind* = [*sy_Begin*, *sy_Semicolon*, *sy_Proof*, *sy_Now*, *sy_Hereby*,
sy_Definition, *sy_End*, *sy_Theorem*, *sy_Reserve*, *sy_Notation*, *sy_Registration*, *sy_Scheme*, *EOT*,
sy_Deffunc, *sy_Defpred*, *sy_Reconsider*, *sy_Consider*, *sy_Then*, *sy_Per*, *sy_Case*, *sy_Suppose*];

1679. We have a few more methods for *specific situations* where errors are likely to occur.

⟨Implementation of parser.pas 1673⟩ +≡

```
procedure MissingWord(fErrNr : integer);
  var lPos: Position;
  begin lPos ← PrevPos; inc(lPos.Col); SynErr(lPos,fErrNr)
  end;

procedure WrongWord(fErrNr : integer);
  begin SynErr(CurPos,fErrNr)
  end;
```

1680. We will want to assert the Parser has encountered a specific token (like a semicolon or “end”) and raise an error if it has not. This will make for much more readable code later on. We should recall *KillItem* (§846) mutates the global state.

[[The *Semicolon* procedure should probably match the *AcceptEnd* procedure — i.e., it should be of the form “if ⟨*Current token is semicolon*⟩ **then** *ReadTokenProc* **else** ⟨*Flag error*⟩”.]]

⟨Implementation of parser.pas 1673⟩ +≡

```
procedure Semicolon;
  begin KillItem;
  if CurWord.Kind ≠ sy_Semicolon then MissingWord(paSemicolonExp);
  if CurWord.Kind = sy_Semicolon then ReadTokenProc;
  end;

procedure AcceptEnd(fPos : Position);
  begin if CurWord.Kind = sy_End then ReadTokenProc
  else begin Error(fPos,paEndExp); MissingWord(paUnpairedSymbol)
  end;
  end;
```

1681. ⟨Error codes for parser 1675⟩ +≡

paUnpairedSymbol = 214; *paEndExp* = 215; *paSemicolonExp* = 330;

1682. Due to the structure of PASCAL, the Parser will frequently be in situations where we consider the **case** of the current kind of token, and for “valid” branches we will want the Parser to consume the current token and move on. For example, if the Parser is looking at an open bracket.

But if the Parser is a panicking mess, then we should raise an error to alert the user.

[[Either some explanation should be offered for the magic number 2546 = #9f2, or it should be stored in a constant (or a WEB macro).]]

⟨Implementation of parser.pas 1673⟩ +≡

```
procedure ReadWord;
  begin Mizassert(2546,StillCorrect); ReadTokenProc
  end;
```

1683. These previous methods can be generalized to an *Accept* procedure which checks whether a given *TokenKind* has “occurred”. If so, just read the next word. Otherwise, flag an error.

When will an error be flagged? If the Parser is panicking, or if the current token does not match the expected token.

⟨Implementation of parser.pas 1673⟩ +≡

function *Occurs*(*fW* : *TokenKind*): *boolean*;

begin *Occurs* \leftarrow *false*;

if *CurWord.Kind* = *fW* **then**

begin *ReadWord*; *Occurs* \leftarrow *true* **end**

end;

procedure *Accept*(*fCh* : *TokenKind*; *fErrNr* : *integer*);

begin if \neg *Occurs*(*fCh*) **then** *MissingWord*(*fErrNr*)

end;

1684. Flagging a semantic error should first check if we are in “panic mode” or not. If we are already panicking, there’s no reason to heap more panicky error messages onto the screen.

⟨Implementation of parser.pas 1673⟩ +≡

procedure *SemErr*(*fErrNr* : *integer*);

begin if *StillCorrect* **then** *ErrImm*(*fErrNr*)

end;

1685. Exercise: For each procedure and function we are about to define in the rest of the Parser, when will an error be raised and by which of these functions?

Section 24.1. EXPRESSIONS

1686. The syntactic classes we're interested in (terms, types, formulas) almost always appear as subexpressions in a formula or some other expression. The Parser works with various procedures to parse these guys as subexpressions: *TermSubexpression* (§1720), *TypeSubexpression* (§1735), *FormulaSubexpression* (§1772). When we need a term (or type or formula) as an expression, as we will in the next section, we use these procedures to construct the abstract syntax tree.

Subsection 24.1.1. Terms

1687. We have a few token kinds which indicate the start of a term:

- (1) identifiers (for variables and private functors),
- (2) infix operators,
- (3) numerals,
- (4) left and right brackets of all sorts,
- (5) the anaphoric “it” constant used in definitions,
- (6) “the” choice operator,
- (7) placeholder variables appearing in private functors and predicates,
- (8) structure symbols.

\langle Parse expressions (`parser.pas` 1687) \equiv
 $\{ \textit{Expressions} \}$

const *TermBegSys*: **set of**

TokenKind = [*Identifier*, *InfixOperatorSymbol*, *Numeral*, *LeftCircumfixSymbol*, *sy_LeftParanthesis*,
sy_It, *sy_LeftCurlyBracket*, *sy_LeftSquareBracket*, *sy_The*, *sy_Dolar*, *Structuresymbol*];

See also sections 1688, 1689, 1690, 1691, 1695, 1713, 1714, 1716, 1724, 1727, 1735, 1736, 1737, 1738, 1739, 1742, 1744, 1746, 1747, 1751, 1752, 1760, 1766, 1767, 1768, 1769, 1770, and 1772.

This code is used in section 1673.

1688. We have a few helper function for *Accept*-ing parentheses. This invokes the *ProcessLeftParanthesis* method for the *gSubexpPtr* (§850) global variable which we recall (§878) is an empty virtual method. So the Parser just “consumes” a left parentheses, and will continue to read tokens while they are left parentheses. The argument passed in will be mutated to track the number of left parentheses consumed.

Similarly, the *CloseParenth* method will have the compiler consume right parentheses, mutating the argument passed in (to decrement the number of right parentheses consumed). This will let us track mismatched parentheses errors.

[[The *ClosedParenth* method should raise an error when the user passes a negative value for *fParenthCnt*, but that may be “too defensive”.]]

\langle Parse expressions (`parser.pas` 1687) \equiv

procedure *OpenParenth*(**var** *fParenthCnt* : *integer*);

begin *fParenthCnt* \leftarrow 0;

while *CurWord.Kind* = *sy_LeftParanthesis* **do**

begin *gSubexpPtr*.*ProcessLeftParanthesis*; *ReadWord*; *inc*(*fParenthCnt*);

end; { *fParenthCnt* \geq 0 }

end;

procedure *CloseParenth*(**var** *fParenthCnt* : *integer*);

begin while (*CurWord.Kind* = *sy_RightParanthesis*) \wedge (*fParenthCnt* > 0) **do**

begin *dec*(*fParenthCnt*); *gSubexpPtr*.*ProcessRightParanthesis*; *ReadWord*;

end; { $\text{old}(fParenthCnt) \geq 0$ implies *fParenthCnt* \geq 0 }

end;

1689. Qualified expressions. Parsing qualified expressions includes a control flow for “exactly” qualified expressions.

We should recall from “Mizar in a nutshell” that the “**exactly**” keyword is reserved but not currently used for anything. The global subexpression pointer is invoking empty virtual methods (§878). So what’s going on?

Well, the only work being done here is in the branch handling “qua”, specifically the *gSubexpPtr* state variable marks the “qua” position (§1581), the next word is read, and then control is handed off to the Parser’s *TypeSubexpression* procedure. The AST is assembled with the *FinishQualifiedTerm* (§1582) method.

⟨ Parse expressions (**parser.pas**) 1687 ⟩ +≡

procedure *TypeSubexpression*; *forward*;

procedure *AppendQua*;

begin while *CurWord.Kind* = *sy_Qua* **do**

begin *gSubexpPtr*↑.*ProcessQua*; *ReadWord*; *TypeSubexpression*; *gSubexpPtr*↑.*FinishQualifiedTerm*;
end;

if *CurWord.Kind* = *sy_Exactly* **then**

begin *gSubexpPtr*↑.*ProcessExactly*; *ReadWord*
end;

end;

1690. Parsing *the contents of* a bracketed term starts a bracketed term (§1622), reads the next word after the start of the bracket, then consumes the maximum number of visible arguments (§842). The *gSubexpPtr* constructs the AST for the bracketed term and its contents (§1623).

The contract for this function is that a left bracket token has been encountered, the Parser has moved on to the next token, and then invoked this function.

⟨ Parse expressions (**parser.pas**) 1687 ⟩ +≡

procedure *GetArguments*(**const** *fArgsNbr*: *integer*); *forward*;

procedure *BracketedTerm*;

begin *gSubexpPtr*↑.*StartBracketedTerm*; *ReadWord*; *GetArguments*(*MaxVisArgNbr*);
gSubexpPtr↑.*FinishBracketedTerm*;

end;

1691. Parsing post-qualified variables (i.e., variables which appear in a Fraenkel term’s “**where**” clause) which consists of a comma-separated list of post-qualified segments.

⟨ Parse expressions (**parser.pas**) 1687 ⟩ +≡

procedure *TermSubexpression*; *forward*;

procedure *FormulaSubexpression*; *forward*;

procedure *ArgumentsTail*(*fArgsNbr* : *integer*); *forward*;

procedure *ProcessPostqualification*;

begin *gSubexpPtr*↑.*StartPostqualification*; { (§1612) }

while *CurWord.Kind* = *sy_Where* **do**

begin repeat ⟨ Process post-qualified segment 1692 ⟩

until *CurWord.Kind* ≠ *sy_Comma*;

end;

end;

1692. Each “segment” in a post-qualification looks like:

$$\langle \text{variable} \rangle \{ ", " \langle \text{variable} \rangle \} ("is" \mid "being") \langle \text{type} \rangle$$

We can process the comma-separated list of variables, then the type ascription term (“is” or “being”), then process the type.

```

define parse_post_qualified_type  $\equiv$  begin ReadWord; TypeSubexpression; end
 $\langle$  Process post-qualified segment 1692  $\rangle \equiv$ 
  gSubexpPtr $\uparrow$ .StartPostQualifyingSegment; { (§1613) } ReadWord;
 $\langle$  Parse post-qualified comma-separated list of variables 1693  $\rangle$ ;
  gSubexpPtr $\uparrow$ .StartPostqualificationSpecyfication; { (§1615) }
  if CurWord.Kind  $\in$  [sy_Is, sy_are] then parse_post_qualified_type;
  gSubexpPtr $\uparrow$ .FinishPostqualifyingSegment; { (§1616) }

```

This code is used in section 1691.

1693. \langle Parse post-qualified comma-separated list of variables 1693 $\rangle \equiv$
repeat gSubexpPtr \uparrow .ProcessPostqualifiedVariable; { (§1614) } Accept(Identifier, paIdentExp1);
until \neg Occurs(sy_Comma)

This code is used in section 1692.

1694. \langle Error codes for parser 1675 $\rangle + \equiv$
 paIdentExp1 = 300; paRightParenthExp1 = 370;

1695. Getting a closed subterm is part of the loop for parsing a term. The intricate relationship of mutually recursive function calls looks something like the following (assuming there are no parsing errors):

Fig. 14. Control flow when parsing a term.

The *GetArguments* parses a comma-separated list of terms. Since each term in the comma-separated list will be a *subterm* of a larger expression, we parse it with *TermSubexpression* (which invokes *GetClosedSubterm* in a mutually recursive relation). If there is a chain of infix operators (like $x + y - z \times \omega$), then *AppendFunc* is invoked on the infix operators.

```

 $\langle$  Parse expressions (parser.pas) 1687  $\rangle + \equiv$ 
procedure GetClosedSubterm;
  begin case CurWord.Kind of
     $\langle$  Get closed subterm of identifier 1696  $\rangle$ ;
     $\langle$  Get closed subterm of structure 1698  $\rangle$ ;
  Numeral: begin gSubexpPtr $\uparrow$ .ProcessNumeralTerm; ReadWord end;
     $\langle$  Get closed subterm of bracketed expression 1700  $\rangle$ ;
  sy_It: begin gSubexpPtr $\uparrow$ .ProcessItTerm; ReadWord end;
  sy_Dolar: begin gSubexpPtr $\uparrow$ .ProcessLocusTerm; ReadWord end;
     $\langle$  Get closed subterm of Fraenkel operator or enumerated set 1702  $\rangle$ ;
     $\langle$  Get closed subterm of choice operator 1706  $\rangle$ ;
  othercases RunTimeError(2133);
  endcases;
end;

```

1696. If we treat an identifier as a term, then it is either a private functor or it is a variable. How do we tell the difference? A private functor starts with an identifier followed by a left parentheses.

Remember, private functors which omit the closing right parentheses should be flagged with a 370 error.

```

⟨ Get closed subterm of identifier 1696 ⟩ ≡
Identifier: if AheadWord.Kind = sy_LeftParenthesis then { treat identifier as private functor }
  begin gSubexpPtr↑.StartPrivateTerm; ReadWord; ReadWord;
  if CurWord.Kind ≠ sy_RightParenthesis then GetArguments(MaxVisArgNbr);
  gSubexpPtr↑.FinishPrivateTerm; Accept(sy_RightParenthesis, paRightParenthExp2);
  end
else { treat identifier as variable }
  begin gSubexpPtr↑.ProcessSimpleTerm; { (§1580) } ReadWord
  end

```

This code is used in section 1695.

1697. ⟨ Error codes for parser 1675 ⟩ +≡
 paRightParenthExp2 = 370;

1698. If the Parser stumbles across the name of a structure when expecting a term, then the Parser should treat it as constructing a new instance of the structure. A 363 error will be raised if the “(” is missing, and a 373 error will be raised if the “)” structure bracket is missing.

```

⟨ Get closed subterm of structure 1698 ⟩ ≡
StructureSymbol: begin gSubexpPtr↑.StartAggregateTerm; ReadWord;
  Accept(sy_StructLeftBracket, paLeftDoubleExp1); GetArguments(MaxVisArgNbr);
  gSubexpPtr↑.FinishAggregateTerm; { (§1625) } Accept(sy_StructRightBracket, paRightDoubleExp1);
  end

```

This code is used in section 1695.

1699. ⟨ Error codes for parser 1675 ⟩ +≡
 paLeftDoubleExp1 = 363; paRightDoubleExp1 = 373;

1700. Encountering a left bracket of some kind — specifically a user-defined left bracket or a “[” — should cause the Parser to look for the contents of a bracketed term (§1690), then a right bracket.

```

⟨ Get closed subterm of bracketed expression 1700 ⟩ ≡
LeftCircumfixSymbol, sy_LeftSquareBracket: begin BracketedTerm;
  case Curword.Kind of
    sy_RightSquareBracket, sy_RightCurlyBracket, sy_RightParenthesis: ReadWord;
  othercases Accept(RightCircumfixSymbol, paRightBraExp1);
  endcases;
  end

```

This code is used in section 1695.

1701. ⟨ Error codes for parser 1675 ⟩ +≡
 paRightBraExp1 = 310;

1702. When the Parser runs into a left curly bracket “{”, we either have encountered a Fraenkel operator or we have encountered a finite set.

```

⟨Get closed subterm of Fraenkel operator or enumerated set 1702⟩ ≡
sy_LeftCurlyBracket: begin gSubexpPtr↑.StartBracketedTerm; { (§1622) }
  ReadWord; TermSubexpression; { (§1720) }
  if (CurWord.Kind = sy_Colon) ∨ (CurWord.Kind = sy_Where) then ⟨Parse a Fraenkel operator 1703⟩
  else ⟨Parse an enumerated set 1705⟩;
end

```

This code is used in section 1695.

1703. Parsing a Fraenkel operator, well, we recall Fraenkel operators look like

$$\{\langle term \rangle \langle post-qualified segment \rangle " : " \langle formula \rangle\}$$

```

⟨Parse a Fraenkel operator 1703⟩ ≡
begin gSubexpPtr↑.StartFraenkelTerm; ProcessPostqualification; gSubexpPtr↑.FinishSample;
  Accept(sy_Colon, paColonExp1); FormulaSubexpression; gSubexpPtr↑.FinishFraenkelTerm;
  Accept(sy_RightCurlyBracket, paRightCurledExp1);
end

```

This code is used in section 1702.

1704. ⟨Error codes for parser 1675⟩ +≡
 paRightCurledExp1 = 372; paColonExp1 = 384;

1705. The Parser can also run into a finite set $\{x_1, \dots, x_n\}$. The braces are treated like any other functor bracket, in the sense that if the right brace } is missing, then a 310 error will be raised.

```

⟨Parse an enumerated set 1705⟩ ≡
begin gSubexpPtr↑.FinishArgument; ArgumentsTail(MaxVisArgNbr - 1);
  gSubexpPtr↑.FinishBracketedTerm;
  case Curword.Kind of
    sy_RightSquareBracket, sy_RightCurlyBracket, sy_RightParanthesis: ReadWord;
  othercases Accept(RightCircumfixSymbol, paRightBraExp1);
  endcases;
end

```

This code is used in section 1702.

1706. Mizar allows “**the**” to be used for selector functors, forgetful functors, choice operators, or simple Fraenkel terms.

Note we are generous *here* with what situations leads to treating “**the**” as a choice operator, because in other parsing procedures any mistakes will be caught there.

```
define choice_operator_cases  $\equiv$  ModeSymbol, AttributeSymbol, sy_Non, sy_LeftParanthesis, Identifier,
    InfixOperatorSymbol, Numeral, LeftCircumfixSymbol, sy_It, sy_LeftCurlyBracket,
    sy_LeftSquareBracket, sy_The, sy_Dolar
```

⟨ Get closed subterm of choice operator 1706 ⟩ \equiv

```
sy_The: begin gSubexpPtr↑.ProcessThe; ReadWord;
case CurWord.Kind of
  SelectorSymbol: ⟨ Parse selector functor 1708 ⟩;
  StructureSymbol: ⟨ Parse forgetful functor or choice of structure type 1709 ⟩;
  sy_Set: ⟨ Parse simple Fraenkel expression or “the set” 1711 ⟩;
  choice_operator_cases: begin gSubexpPtr↑.StartChoiceTerm; TypeSubexpression;
    gSubexpPtr↑.FinishChoiceTerm;
  end
othercases begin gSubexpPtr↑.InsertIncorrTerm; WrongWord(paWrongAfterThe)
end;
endcases;
end
```

This code is used in section 1695.

1707. ⟨ Error codes for parser 1675 ⟩ $+\equiv$

```
paWrongAfterThe = 320;
```

1708. ⟨ Parse selector functor 1708 ⟩ \equiv

```
begin gSubexpPtr↑.StartSelectorTerm; ReadWord; { parses “the ⟨selector⟩” }
if Occurs(sy_Of) then TermSubexpression; { parses “of ⟨Term⟩” }
  gSubexpPtr↑.FinishSelectorTerm; { builds AST subtree }
end
```

This code is used in section 1706.

1709. A forgetful functor always looks like

“**the**” ⟨structure⟩ “**of**” ⟨term⟩

On the other hand, the choice operator acting on a structure type looks similar. We should distinguish these two by the presence of the keyword “**of**”.

⟨ Parse forgetful functor or choice of structure type 1709 ⟩ \equiv

```
if AheadWord.Kind = sy_Of then { forgetful functor }
  begin gSubexpPtr↑.StartForgetfulTerm; ReadWord; Accept(sy_Of, paOfExp); TermSubexpression;
    gSubexpPtr↑.FinishForgetfulTerm;
  end
else { choice operator, e.g., “the multMagma” }
  begin gSubexpPtr↑.StartChoiceTerm; TypeSubexpression; gSubexpPtr↑.FinishChoiceTerm;
  end
```

This code is used in section 1706.

1710. ⟨ Error codes for parser 1675 ⟩ $+\equiv$

```
paOfExp = 256;
```

1711. Mizar allows “the set of” to start a simple Fraenkel expression. But we could also refer to “the set” as the set chosen by the axiom of choice.

```

⟨ Parse simple Fraenkel expression or “the set” 1711 ⟩ ≡
  if AheadWord.Kind = sy_Of then { simple Fraenkel expression }
    begin ReadWord; { set }
      ReadWord; { of }
      gSubexpPtr↑.StartSimpleFraenkelTerm; Accept(sy_All, paAllExp); TermSubexpression;
      gSubexpPtr↑.StartFraenkelTerm; ProcessPostqualification; gSubexpPtr↑.FinishSimpleFraenkelTerm;
    end
  else { “the set” }
    begin gSubexpPtr↑.StartChoiceTerm; TypeSubexpression; gSubexpPtr↑.FinishChoiceTerm; end

```

This code is used in section 1706.

1712. ⟨ Error codes for parser 1675 ⟩ +≡
 paAllExp = 275;

1713. Subexpression object’s *FinishArgument* (§1585) is invoked, which pushes a term onto the *Term* stack. This will invoke the *AppendQua* (§1689) method and expect a closed parentheses afterwards (§1688).

Possible bug: what should happen when *fParenthCnt* is zero or negative?

```

⟨ Parse expressions (parser.pas) 1687 ⟩ +≡
procedure CompleteArgument(var fParenthCnt : integer);
  begin gSubexpPtr↑.FinishArgument;
  repeat AppendQua; CloseParenth(fParenthCnt);
  until CurWord.Kind ≠ sy_Qua; { ∧(CurWord.Kind ≠ sy_Exactly) }
end;

```

1714. Keep parsing “infix operators”. When the current token is an infix operator, this will consume the arguments to its right, then iterate. It’s also worth remembering that *gExpPtr* (§850) was a global variable declared back in `syntax.pas`, and the *CreateSubexpression* (§1671) mutates the *gSubexpPtr* variable. Now we see it in action.

This invokes the *ProcessLeftParenthesis* method for the *gSubexpPtr* (§850) global variable which we recall (§878) is an empty virtual method. So the Parser just “consumes” a left parentheses.

Note that the **case** expression considers the type of *TokenKind* (§884) of the current word. But it is not exhaustive.

There is a comment in Polish, “Chyba po prostu TermSubexpression”, which Google translated into English as “I guess it’s just Term Subexpression”. I swapped this in the code below.

```

⟨Parse expressions (parser.pas) 1687⟩ +≡
procedure AppendFunc(var fParenthCnt : integer);
begin while CurWord.Kind = InfixOperatorSymbol do
  begin gSubexpPtr↑.StartLongTerm; { (§1593) }
  repeat gSubexpPtr↑.ProcessFunctorSymbol; { (§1609) }
    ReadWord;
  case CurWord.Kind of
    sy_LeftParanthesis:
      begin { parenthesised term(s) }
        gSubexpPtr↑.ProcessLeftParenthesis; ReadWord; { consume the left paren }
        GetArguments(MaxVisArgNbr); { (§1738) }
        gSubexpPtr↑.ProcessRightParenthesis; Accept(sy_RightParanthesis, paRightParenthExp3);
          { consume matching right paren }
        end;
      Identifier, Numeral, LeftCircumfixSymbol, sy_It, sy_LeftCurlyBracket, sy_LeftSquareBracket, sy_The,
        sy_Dolar, StructureSymbol: { I guess it’s just Term Subexpression }
      begin gExpPtr↑.CreateSubexpression; { (§1671) }
        GetClosedSubterm; { (§1695) }
        gSubexpPtr↑.FinishArgument; { (§1585) }
        KillSubexpression; { (§844) }
      end;
    endcases;
    gSubexpPtr↑.FinishArgList; { (§1610) }
  until CurWord.Kind ≠ InfixOperatorSymbol;
  gSubexpPtr↑.FinishLongTerm; { (§1597) }
  CompleteArgument(fParenthCnt); { (§1713) }
end;
end;

1715. ⟨Error codes for parser 1675⟩ +≡
  paRightParenthExp3 = 370;

```

1716. Parse terms with infix operators. Note this appears to parse infix operators as left-associative (e.g., $x + y + z$ is parsed as $(x + y) + z$).

⟨ Parse expressions (`parser.pas`) 1687 ⟩ +≡

```
procedure ProcessArguments;
  var lParenthCnt: integer;
  begin OpenParenth(lParenthCnt);
  case CurWord.Kind of
    Identifier, Numeral, LeftCircumfixSymbol, sy_It, sy_LeftCurlyBracket, sy_LeftSquareBracket, sy_The,
      sy_Dolar, StructureSymbol:
      begin GetClosedSubterm; CompleteArgument(lParenthCnt); end;
    InfixOperatorSymbol: ;
  othercases begin gSubexpPtr↑.InsertIncorrTerm; gSubexpPtr↑.FinishArgument;
    WrongWord(paWrongTermBeg);
  end;
endcases;
  ⟨ Keep parsing as long as there is an infix operator to the right 1718 ⟩;
  ⟨ Check every remaining open (left) parentheses has a corresponding partner 1719 ⟩;
end;
```

1717. ⟨ Error codes for parser 1675 ⟩ +≡

paWrongTermBeg = 397;

1718. ⟨ Keep parsing as long as there is an infix operator to the right 1718 ⟩ ≡

```
repeat AppendFunc(lParenthCnt);
  if CurWord.Kind = sy_Comma then
    begin ArgumentsTail(MaxVisArgNbr - 1);
    if (lParenthCnt > 0) ∧ (CurWord.Kind = sy_RightParanthesis) then
      begin dec(lParenthCnt); gSubexpPtr↑.ProcessRightParanthesis; ReadWord;
      end;
    end;
  until CurWord.Kind ≠ InfixOperatorSymbol
```

This code is used in section 1716.

1719. ⟨ Check every remaining open (left) parentheses has a corresponding partner 1719 ⟩ ≡

```
while lParenthCnt > 0 do
  begin gSubexpPtr↑.ProcessRightParanthesis; Accept(sy_RightParanthesis, paRightParenthExp1);
  dec(lParenthCnt);
  end
```

This code is used in section 1716.

1720. Term subexpressions. The Parser wants a term as a subexpression in a formula or attribute cluster or some similar situation. The term specifically is just a *component* of the expression. We should recall from Figure 14 (§1695) that this is a critical part of parsing terms.

⟨Parse term subexpressions (parser.pas) 1720⟩ ≡

```

procedure TermSubexpression;
  var lParenthCnt: integer;
  begin gExpPtr↑.CreateSubexpression; OpenParenth(lParenthCnt); { (§1688) }
  case CurWord.Kind of
    Identifier, Numeral, LeftCircumfixSymbol, sy_It, sy_LeftCurlyBracket, sy_LeftSquareBracket, sy_The,
      sy_Dolar, StructureSymbol:
      begin GetClosedSubterm; CompleteArgument(lParenthCnt); { (§1713) }
      end;
    InfixOperatorSymbol: { skip } ;
  othercases ⟨Raise error over invalid term subexpression 1721⟩;
  endcases;
  AppendFunc(lParenthCnt); { (§1714) }
  while lParenthCnt > 0 do ⟨Parse arguments to the right 1722⟩;
  gSubexpPtr↑.FinishTerm; KillSubexpression;
  end;

```

This code is used in section 1736.

1721. ⟨Raise error over invalid term subexpression 1721⟩ ≡

```

begin gSubexpPtr↑.InsertIncorrTerm; gSubexpPtr↑.FinishArgument; WrongWord(paWrongTermBeg);
end

```

  if CurWord.Kind ≠ InfixOperatorSymbol then MissingWord(paFuncExp3);
  AppendFunc(lParenthCnt);
end

```

This code is used in section 1720.

1723. ⟨Error codes for parser 1675⟩ +≡

```

paFuncExp3 = 302; paRightParenthExp10 = 370;

```

Subsection 24.1.2. Types and Attributes

1724. Types and attributes are closely related, when it comes to parsing Mizar. After all, we can add an adjective to a type and we expect it to be “a type”.

An adjective cluster is just one or more (possibly negated) attribute.

⟨Parse expressions (parser.pas) 1687⟩ +≡

⟨Process attributes (parser.pas) 1725⟩

```

procedure GetAdjectiveCluster;
  begin gSubexpPtr↑.StartAdjectiveCluster; ProcessAttributes; gSubexpPtr↑.FinishAdjectiveCluster;
  end;

```

1725. Parsing an attribute amounts to:

- (1) handling a leading “non”
- (2) handling attribute arguments (which always occurs *before* the attribute)
- (3) handling the attribute.

```

define kind_is_radix_type(#)  $\equiv$  (#  $\in$  [sy_Set, ModeSymbol, StructureSymbol])
define ahead_is_attribute_argument  $\equiv$ 
  (CurWord.Kind  $\in$  (TermBegSys - [sy_LeftParanthesis, StructureSymbol]))  $\vee$ 
  ((CurWord.Kind = sy_LeftParanthesis)  $\wedge$   $\neg$ (kind_is_radix_type(AheadWord.Kind)))  $\vee$ 
  ((CurWord.Kind = StructureSymbol)  $\wedge$  (AheadWord.Kind = sy_StructLeftBracket))
 $\langle$  Process attributes (parser.pas) 1725  $\rangle \equiv$ 
procedure ProcessAttributes;
begin while (CurWord.Kind  $\in$  [AttributeSymbol, sy_Non])  $\vee$  ahead_is_attribute_argument do

  StructureSymbol:  $\langle$  Parse structure as radix type 1731  $\rangle$ ;
  othercases begin MissingWord(paWrongRadTypeBeg); gSubexpPtr $\uparrow$ .InsertIncorrType end;
endcases;
 $\langle$  Close the parentheses 1734  $\rangle$ ;
gSubexpPtr $\uparrow$ .FinishType;
end;

```

1728. \langle Error codes for parser 1675 $\rangle + \equiv$
paWrongRadTypeBeg = 398;

1729. $\langle \text{Parse mode as radix type } 1729 \rangle \equiv$
begin $lSymbol \leftarrow CurWord.Nr$; $ReadWord$;
if $CurWord.Kind = sy_Of$ **then**
 if $ModeMaxArgs.fList\uparrow[lSymbol] = 0$ **then** $WrongWord(paUnexpOf)$
 else begin $ReadWord$; $GetArguments(ModeMaxArgs.fList\uparrow[lSymbol])$ **end**;
end

This code is used in section 1727.

1730. $\langle \text{Error codes for parser } 1675 \rangle + \equiv$
 $paUnexpOf = 183$;

1731. $\langle \text{Parse structure as radix type } 1731 \rangle \equiv$
begin $lSymbol \leftarrow CurWord.Nr$; $ReadWord$;
if $CurWord.Kind = sy_Over$ **then**
 if $StructModeMaxArgs.fList\uparrow[lSymbol] = 0$ **then** $WrongWord(paUnexpOver)$
 else begin $ReadWord$; $GetArguments(StructModeMaxArgs.fList\uparrow[lSymbol])$ **end**;
end

This code is used in section 1727.

1732. $\langle \text{Error codes for parser } 1675 \rangle + \equiv$
 $paUnexpOver = 184$;

1733. $\langle \text{Parse optional left-paren } 1733 \rangle \equiv$
if $CurWord.Kind = sy_LeftParanthesis$ **then**
 begin $gSubexpPtr\uparrow.ProcessLeftParenthesis$; $ReadWord$; $inc(lParenthCnt)$;
 end

This code is used in section 1727.

1734. $\langle \text{Close the parentheses } 1734 \rangle \equiv$
if $lParenthCnt > 0$ **then**
 begin $gSubexpPtr\uparrow.ProcessRightParenthesis$; $Accept(sy_RightParanthesis, paRightParenthExp1)$;
 end

This code is used in section 1727.

1735. Type subexpressions. Now the Parser needs a type as a subexpression in a larger expression (e.g., the specification for a definition, or in a formula of the form “ $\langle Term \rangle$ is $\langle Type \rangle$ ”). We basically get the adjectives with $GetAdjectiveCluster$, then we get the radix type with $RadixTypeSubexpression$.

$\langle \text{Parse expressions (parser.pas) } 1687 \rangle + \equiv$

procedure $TypeSubexpression$;

begin $gExpPtr\uparrow.CreateSubexpression$; $gSubexpPtr\uparrow.StartType$; $gSubexpPtr\uparrow.StartAttributes$;
 $GetAdjectiveCluster$; $RadixTypeSubexpression$;
 $gSubexpPtr\uparrow.CompleteAttributes$; $gSubexpPtr\uparrow.CompleteType$;
 $KillSubexpression$;
end;

1736. Aside: parsing term subexpressions. The code for parsing term subexpressions (§1720) appears here in the code for the Parser, but it felt out of place. I thought it best to place it at the end of the subsection on parsing Term expressions (as it is the pinnacle of Term parsing), rather than leave it here.

$\langle \text{Parse expressions (parser.pas) } 1687 \rangle + \equiv$

$\langle \text{Parse term subexpressions (parser.pas) } 1720 \rangle$

1737. This will parse *fArgsNbr* comma separated terms. It's used to parse the arguments "to the right" of a term, for parsing the contents of an enumerated set (e.g., $\{x, y, z, w\}$), among many other places.

We should recall that the *StartArgument* method is empty.

```

⟨ Parse expressions (parser.pas) 1687 ⟩ +≡
procedure ArgumentsTail(fArgsNbr : integer);
  begin while (fArgsNbr > 0) ∧ Occurs(sy_Comma) do
    begin gSubexpPtr↑.StartArgument; TermSubexpression; gSubexpPtr↑.FinishArgument;
      dec(fArgsNbr);
    end;
  end;

```

1738. Attributes, terms, predicates have terms as arguments. This relies upon the *FinishArguments* method (§1585).

```

⟨ Parse expressions (parser.pas) 1687 ⟩ +≡
procedure GetArguments(const fArgsNbr: integer);
  begin if fArgsNbr > 0 then
    begin TermSubexpression; gSubexpPtr↑.FinishArgument; ArgumentsTail(fArgsNbr − 1);
    end;
  end;

```

Subsection 24.1.3. Formulas

1739. Quantified variables looks like

$$\langle \text{Variable} \rangle \{ \text{" , " } \langle \text{Variable} \rangle \} [(\text{"be"|"being"}) \langle \text{Type} \rangle]$$

The parsing routine follows the grammar fairly faithfully.

```

⟨ Parse expressions (parser.pas) 1687 ⟩ +≡
procedure QuantifiedVariables;
  begin repeat gSubexpPtr↑.StartQualifiedSegment; ReadWord;
    ⟨ Parse comma-separated variables for quantified variables 1740 ⟩;
    gSubexpPtr↑.StartQualifyingType;
    if Occurs(sy_Be) ∨ Occurs(sy_Being) then TypeSubexpression;
    gSubexpPtr↑.FinishQualifiedSegment;
  until CurWord.Kind ≠ sy_Comma;
  end;

```

1740. ⟨ Parse comma-separated variables for quantified variables 1740 ⟩ ≡
repeat *gSubexpPtr*↑.ProcessVariable; Accept(Identifier, *paIdentExp2*);
until ¬Occurs(*sy_Comma*)

This code is used in section 1739.

1741. ⟨ Error codes for parser 1675 ⟩ +≡
paIdentExp2 = 300;

1742. The existential formula looks like

$$\text{ex } \langle \text{Quantified-Variables} \rangle \text{ st } \langle \text{Formula} \rangle$$

The Parser implements it quite faithfully.

⟨ Parse expressions (parser.pas) 1687 ⟩ +≡

procedure *ExistentialFormula*;

```
begin gSubexpPtr↑.StartExistential; QuantifiedVariables;
gSubexpPtr↑.FinishQuantified; Accept(sy_St, paStExp); FormulaSubexpression;
gSubexpPtr↑.FinishExistential;
end;
```

1743. ⟨ Error codes for parser 1675 ⟩ +≡

paStExp = 387;

1744. Universally quantified formulas are tricky because both

$$\text{for } \langle \text{Quantified-Variables} \rangle \text{ holds } \langle \text{Formula} \rangle$$

and

$$\text{for } \langle \text{Quantified-Variables} \rangle \text{ st } \langle \text{Formula} \rangle \text{ holds } \langle \text{Formula} \rangle$$

are acceptable. Furthermore, we may include multiple “for $\langle \text{Quantified-Variables} \rangle$ ” (possibly with “st $\langle \text{Formula} \rangle$ ” restrictions) before arriving at the single “holds $\langle \text{Formula} \rangle$ ”. The trick is to parse this as

$$\text{for } \langle \text{Quantified-Variables} \rangle [\text{st } \langle \text{Formula} \rangle] [\text{holds}] \langle \text{Formula} \rangle$$

so the recursive call to parse the final formula enables us to parse another quantified formula.

⟨ Parse expressions (parser.pas) 1687 ⟩ +≡

procedure *UniversalFormula*;

```
begin gSubexpPtr↑.StartUniversal; QuantifiedVariables; gSubexpPtr↑.FinishQuantified;
if CurWord.Kind = sy_St then
begin gSubexpPtr↑.StartRestriction; ReadWord; FormulaSubexpression;
gSubexpPtr↑.FinishRestriction;
end;
case CurWord.Kind of
sy_Holds: begin gSubexpPtr↑.ProcessHolds; ReadWord end;
sy_For, sy_Ex: ; { fallthrough }
othercases begin gSubexpPtr↑.InsertIncorrFormula; MissingWord(paWrongScopeBeg)
end;
endcases;
FormulaSubexpression; gSubexpPtr↑.FinishUniversal;
end;
```

1745. ⟨ Error codes for parser 1675 ⟩ +≡

paWrongScopeBeg = 340;

1746. The Parser’s current token is either “=” or a predicate symbol. Then we should parse “the right-hand side” of the equation (or formula). The current token’s Symbol number is passed as the argument to this procedure.

It’s worth recalling the definition of *TermBegSys* (§1687) which is all the token kinds for starting a term. If the next token is a term, then *GetArguments* is invoked to parse them.

⟨ Parse expressions (parser.pas) 1687 ⟩ +≡

procedure *ConditionalTail*; *forward*;

procedure *CompleteRightSideOfThePredicativeFormula*(*aPredSymbol* : integer);

begin *gSubexpPtr*↑.ProcessRightSideOfPredicateSymbol; *ReadWord*;

if *CurWord.Kind* ∈ *TermBegSys* **then** *GetArguments*(*PredMaxArgs.fList*↑[*aPredSymbol*]);

gSubexpPtr↑.FinishRightSideOfPredicativeFormula;

end;

1747. Recall a “multi-predicative formula” is something of the form $a \leq x \leq b$. More generally, we could imagine the grammar for such a formula resembles:

$$\langle \text{Formula} \rangle \{ \langle \text{Multi-Predicate} \rangle \langle \text{Term-List} \rangle \}$$

The Parser’s current token is *⟨Multi-Predicate⟩*, and we want to keep parsing until the entire multi-predicative formula has been parsed.

We should mention (because I have not seen it discussed anywhere) Mizar allows “does not” and “do not” in formulas (for example, “Y does not overlap X ∧ Z”), but Mizar **does not** support “does” (or “do”) without the “not”. A 401 error would be raised.

Grammatically, this is known as “do-support”, and Mizar uses it for negating predicates. The verb following the “do” is a “bare infinitive” (which is why Mizar allows an “infinitive” for predicates). This makes sense when the predicate uses a “finite verb”. For “non-finite verb forms”, it is idiomatic English to just negate the verb (as in “Not knowing what that means, I just smile and nod” and “It would be a crime not to learn grammar”).

⟨ Parse expressions (parser.pas) 1687 ⟩ +≡

procedure *CompleteMultiPredicativeFormula*;

end

This code is used in section 1760.

1765. ⟨ Error codes for parser 1675 ⟩ \equiv
paRightParenthExp4 = 370;

1766. Precedence for logical connectives. We will now “hardcode” the precedence for logical connectives into the Mizar Parser. Negations (“**not**”) binds tighter than conjunction (“**&**”), which binds tighter than disjunction (“**or**”), which binds tighter than implication (“**implies**” and “**iff**”).

At this point, for the formula “A & B”, the Parser has parsed a formula (“A”), and we want to parse possible conjunctions. The current token will be “&”. If not, then the Parser does nothing: it’s “done”.

We will parse conjunction as left associative — so “A & B & C” parses as “(A & B) & C”.

⟨ Parse expressions (parser.pas) 1687 ⟩ +≡

procedure *ConjunctiveTail*;

```

begin while (CurWord.Kind = sy_Ampersand)  $\wedge$  (AheadWord.Kind  $\neq$  sy_Ellipsis) do
  begin gSubexpPtr↑.ProcessBinaryConnective; ReadWord; ViableFormula; KillSubexpression;
  gSubexpPtr↑.FinishBinaryFormula;
  end;
end;

```

1767. Mizar parses flexary conjunctions (“ $\Phi[0] \& \dots \& \Phi[n]$ ”) as weaker than “ordinary conjunction”. For example “ $\Psi \& \Phi[0] \& \dots \& \Phi[n]$ ” parses as “ $(\Psi \& \Phi[0]) \& \dots \& \Phi[n]$ ”.

If the user accidentally forgets the ampersand after the ellipses (“ $\Phi[0] \& \dots \Phi[n]$ ”), a 402 error will be raised.

⟨ Parse expressions (parser.pas) 1687 ⟩ +≡

procedure *FlexConjunctiveTail*;

```

begin ConjunctiveTail;
if CurWord.Kind = sy_Ampersand then
  begin Assert(AheadWord.Kind = sy_Ellipsis); ReadWord; ReadWord; Accept(sy_Ampersand, 402);
  gSubexpPtr↑.ProcessFlexConjunction; ViableFormula; ConjunctiveTail; KillSubexpression;
  gSubexpPtr↑.FinishFlexConjunction;
  end;
end;

```

1768. Disjunction binds weaker than flexary conjunction (which binds weaker than ordinary conjunction).

As for ordinary conjunction, Mizar parses multiple disjunctions as left associative. So “A or B or C” parses as “(A or B) or C”.

⟨ Parse expressions (parser.pas) 1687 ⟩ +≡

procedure *DisjunctiveTail*;

```

begin FlexConjunctiveTail;
while (CurWord.Kind = sy_Or)  $\wedge$  (AheadWord.Kind  $\neq$  sy_Ellipsis) do
  begin gSubexpPtr↑.ProcessBinaryConnective; ReadWord; ViableFormula; FlexConjunctiveTail;
  KillSubexpression; gSubexpPtr↑.FinishBinaryFormula;
  end;
end;

```

1769. Parsing a disjunction will have the Parser’s current token be “or” only if the next token is an ellipsis (“...”), which is precisely the signal for a flexary disjunction. When the current token is not an “or”, then the Parser does nothing (its work is done).

When the user forgets an “or” after ellipsis (e.g., writing “A or ... C”), a 401 error will be raised.

⟨Parse expressions (parser.pas) 1687⟩ +≡

```

procedure FlexDisjunctiveTail;
  begin DisjunctiveTail;
  if CurWord.Kind = sy.Or then
    begin Assert(AheadWord.Kind = sy.Ellipsis); ReadWord; ReadWord; Accept(sy.Or, 401);
    gSubexpPtr↑.ProcessFlexDisjunction; ViableFormula; DisjunctiveTail; KillSubexpression;
    gSubexpPtr↑.FinishFlexDisjunction;
    end;
  end;

```

1770. Mizar parses “implies” and “iff” with lower precedence than “or”, matching common Mathematical practice. Working Mathematicians read “A or B implies C” as “(A or B) implies C”. We impose this precedence with the *FlexDisjunctiveTail* parsing the remaining disjunctions before checking for “iff” or “implies”.

Mizar accepts one “topmost” implication connective. So “A implies B implies C” would be illegal (a 336 error would be raised). You would have to insert parentheses to make this parseable by Mizar (i.e., “A implies (B implies C)”). This makes sense for implication, but there is a compelling argument that “A iff B iff C” could be parsed as “(A iff B) & (B iff C)” — that latter formula *could* be parsed properly by Mizar.

⟨Parse expressions (parser.pas) 1687⟩ +≡

```

procedure ConditionalTail;
  begin FlexDisjunctiveTail;
  case CurWord.Kind of
    sy.Implies, sy.Iff: begin gSubexpPtr↑.ProcessBinaryConnective; ReadWord; ViableFormula;
    FlexDisjunctiveTail; KillSubexpression; gSubexpPtr↑.FinishBinaryFormula;
    case CurWord.Kind of
      sy.Implies, sy.Iff: WrongWord(paUnexpConnective);
    endcases;
    end;
  endcases;
  end;

```

1771. ⟨Error codes for parser 1675⟩ +≡

paUnexpConnective = 336;

1772. Formula subexpressions. When the Parser needs a formula as a subexpression for a larger expression — like when it parses a Fraenkel term (an expression), the Parser will need to parse

$$\{\langle \text{Term} \rangle \langle \text{Qualifying-Segment} \rangle : \langle \text{Formula-Subexpression} \rangle\}$$

This will also serve as the “workhorse” for parsing a formula expression.

⟨Parse expressions (parser.pas) 1687⟩ +≡

```

procedure FormulaSubexpression;
  begin ViableFormula; ConditionalTail; KillSubexpression;
  end;

```

Section 24.2. COMMUNICATION WITH ITEMS

1773. When the Parser constructs the AST for a term, the workflow is as follows:

- (1) Allocate a new *extExpression* object, and update *gExprPtr* to point at it.
- (2) Using the *gExprPtr* to allocate a new *extSubexp* object, and update the *gSubexpPtr* to point at it.
- (3) The Parser will invoke methods for the *gSubexpPtr*'s reference to build the AST. The result will be stored in a state variable (like *gLastTerm* or *gLastType*).
- (4) There will be residual objects allocated, stored in the fields of *gSubexpPtr* and *gExpPtr*. We need to clean those up, freeing them, by invoking *KillExpression* and *KillSubexpression*.

So each of these methods have the following template: allocate a new expression object, update the *gExpPtr* to point to it, parse something, then free the *gExpPtr* using the *KillExpression* procedure.

\langle Communicate with items (parser.pas) 1773 $\rangle \equiv$
 $\{$ *Communication with items* $\}$

procedure *TermExpression*;

begin *gItemPtr* \uparrow .*CreateExpression*(*exTerm*); *TermSubexpression*; *KillExpression*;
 end;

procedure *TypeExpression*;

begin *gItemPtr* \uparrow .*CreateExpression*(*exType*); *TypeSubexpression*; *KillExpression*;
 end;

procedure *FormulaExpression*;

begin *gItemPtr* \uparrow .*CreateExpression*(*exFormula*); *FormulaSubexpression*; *KillExpression*;
 end;

This code is used in section 1673.

Section 24.3. MISCELLANEOUS

1774. Parsing a label. When the Parser is looking at a label, the *gItemPtr* will construct the label. The Parser still needs to move past the “*<identifier>:*” two tokens.

```

<Process miscellany (parser.pas) 1774> ≡
  { Miscellaneous }
procedure ProcessLab;
begin gItemPtr↑.ProcessLabel; { (§1545) }
if (CurWord.Kind = Identifier) ∧ (AheadWord.Kind = sy_Colon) then
  begin ReadWord; ReadWord end;
end;

```

See also sections 1775, 1776, 1777, 1778, 1779, 1782, 1785, 1787, 1789, and 1790.

This code is used in section 1673.

1775. Telling the *gItemPtr* state variable we are about to parse a sentence just invokes the *StartSentence* (§1460) method, then the Parser parses the formula, and the *gItemPtr* “finishes” the sentence (which is an empty method).

```

<Process miscellany (parser.pas) 1774> +≡
procedure ProcessSentence;
begin gItemPtr↑.StartSentence; FormulaExpression; gItemPtr↑.FinishSentence;
end;

```

1776. When the Parser expected a sentence but something unexpected happened, specifically an unexpected statement has cross the Parser’s path. When that statement has encountered an unjustified “per cases”. We just create a new formula expression, and specifically an “incorrect formula”.

```

<Process miscellany (parser.pas) 1774> +≡
procedure InCorrSentence;
begin gItemPtr↑.StartSentence; gItemPtr↑.CreateExpression(exFormula);
  gExpPtr↑.CreateSubexpression; gSubexpPtr↑.InsertIncorrFormula; KillSubexpression; KillExpression;
  gItemPtr↑.FinishSentence;
end;

```

1777. The Parser attempts to recover (or at least, report) an unexpected item when expecting a statement. Specifically, a “per cases” appears when it should not.

```

<Process miscellany (parser.pas) 1774> +≡
procedure InCorrStatement;
begin gItemPtr↑.ProcessLabel; gItemPtr↑.StartRegularStatement; InCorrSentence;
end;

```

1778. The Parser is looking at either

let $\langle Variables \rangle$ **being** $\langle Type \rangle$ **such that** $\langle Hypotheses \rangle$

or

assume that $\langle Hypotheses \rangle$

Specifically, the Parser has arrived at the “ $\langle Hypotheses \rangle$ ” bit and needs to parse it. The $\langle Hypotheses \rangle$ generically looks like

$\langle Hypotheses \rangle = [\langle label \rangle] \langle Formula \rangle \{ \text{and } \langle Hypotheses \rangle \}$

That is to say, a bunch of (possibly labeled) formulas joined together by “and” keywords.

\langle Process miscellany (parser.pas) 1774 $\rangle + \equiv$

procedure *ProcessHypotheses*;

begin repeat *ProcessLab*; *ProcessSentence*; *gItemPtr*↑.*FinishHypothesis*;

until $\neg \text{Occurs}(sy_And)$

end;

1779. An assumption is either collective (using hypotheses) or singular (a single, possibly labeled, formula).

\langle Process miscellany (parser.pas) 1774 $\rangle + \equiv$

procedure *Assumption*;

begin if *CurWord.Kind* = *sy_That* **then** \langle Parse collective assumption 1780 \rangle

else \langle Parse single assumption 1781 \rangle ;

gItemPtr↑.*FinishAssumption*;

end;

1780. \langle Parse collective assumption 1780 $\rangle \equiv$

begin *gItemPtr*↑.*StartCollectiveAssumption*; { (§1476) } *ReadWord*; *ProcessHypotheses*

end

This code is used in section 1779.

1781. \langle Parse single assumption 1781 $\rangle \equiv$

begin *ProcessLab*; *ProcessSentence*; *gItemPtr*↑.*FinishHypothesis*; { (§1540) }

end

This code is used in section 1779.

1782. **Fixed variables.** Existential elimination in Mizar looks like

consider $\langle Fixed-variables \rangle$ **such that** $\langle Formula \rangle$

The $\langle Fixed-variables \rangle$ is just a comma-separated list of segments.

\langle Process miscellany (parser.pas) 1774 $\rangle + \equiv$

procedure *FixedVariables*;

begin *gItemPtr*↑.*StartFixedVariables*;

repeat \langle Parse segment of fixed variables 1783 \rangle ;

until $\neg \text{Occurs}(sy_Comma)$;

gItemPtr↑.*FinishFixedVariables*;

end;

1783. And a “fixed” segment is just a comma-separated list of variables. This is either implicitly qualified (i.e., they are all reserved variables) or explicitly qualified (i.e., there is a “being” or “be”, followed by a type). A 300 error will be raised if the comma-separated list of variables encounters something other than an identifier.

```

⟨ Parse segment of fixed variables 1783 ⟩ ≡
  gItemPtr↑.StartFixedSegment;
  repeat gItemPtr↑.ProcessFixedVariable; Accept(Identifier, paIdentExp4);
  until ¬Occurs(sy_Comma);
  gItemPtr↑.ProcessBeing; { parse the type qualification }
  if Occurs(sy_Be) ∨ Occurs(sy_Being) then TypeExpression;
  gItemPtr↑.FinishFixedSegment

```

This code is used in section 1782.

1784. ⟨ Error codes for parser 1675 ⟩ +≡
 paIdentExp4 = 300;

1785. Parsing ‘consider’ statements. The Parser is trying to parse a “consider” statement or a “given” statement. The Parser will try to parse

$$\langle \textit{Fixed-Variables} \rangle \text{ such that } \langle \textit{Formula} \rangle \{ \text{ and } \langle \textit{Formula} \rangle \}$$

If the user forgot the “such” keyword, a 403 error will be raised. If the user forgot the “that” keyword, a 350 error will be raised.

```

⟨ Process miscellany (parser.pas) 1774 ⟩ +≡
procedure ProcessChoice;
  begin FixedVariables; Accept(sy_Such, paSuchExp); Accept(sy_That, paThatExp2);
  repeat gItemPtr↑.StartCondition; ProcessLab; ProcessSentence; gItemPtr↑.FinishCondition;
  until ¬Occurs(sy_And);
  gItemPtr↑.FinishChoice;
end;

```

1786. ⟨ Error codes for parser 1675 ⟩ +≡
 paThatExp2 = 350; paSuchExp = 403;

1787. Parsing ‘let’ statements. The Parser is looking at the “let” token. There are two possible statements

$$\text{let } \langle \textit{Fixed-variables} \rangle;$$

or possibly with assumptions

$$\text{let } \langle \textit{Fixed-variables} \rangle \text{ such that } \langle \textit{Hypotheses} \rangle;$$

If the user forgot “that” but included a “such” after the fixed-variables, a 350 error is raised.

```

⟨ Process miscellany (parser.pas) 1774 ⟩ +≡
procedure Generalization;
  begin ReadWord; FixedVariables;
  if Occurs(sy_Such) then
    begin gItemPtr↑.StartAssumption; Accept(sy_That, paThatExp1); ProcessHypotheses;
    gItemPtr↑.FinishAssumption;
    end;
  end;

```

1788. \langle Error codes for parser 1675 $\rangle + \equiv$
 $paThatExp1 = 350;$

1789. Parsing ‘given’ statements. The Parser is looking at the “given” token currently. This is the same as “assume ex \vec{x} st $\Phi[\vec{x}]$; then consider \vec{x} such that $\Phi[\vec{x}]$;”.

\langle Process miscellany (parser.pas) 1774 $\rangle + \equiv$
procedure *ExistentialAssumption*;
 begin $gBlockPtr \uparrow.CreateItem(itExistentialAssumption);$ *ReadWord*; *ProcessChoice*;
 end;

1790. The Parser is looking at either “canceled;” or “canceled $\langle number \rangle$;”.

\langle Process miscellany (parser.pas) 1774 $\rangle + \equiv$
procedure *Canceled*;
 begin $gBlockPtr \uparrow.CreateItem(itCanceled);$ *ReadWord*;
 if $CurWord.Kind = Numeral$ **then** *ReadWord*;
 $gItemPtr \uparrow.FinishTheorem$;
 end;

Section 24.4. SIMPLE JUSTIFICATIONS

1791. The Parser is looking at “by” and now needs to parse the list of references. If the user tries to use something other than a label’s identifier as a reference, then a 308 error will be raised.

⟨ Parse simple justifications (*parser.pas*) 1791 ⟩ ≡
 { *Simple Justifications* }
procedure *GetReferences*;
begin *gItemPtr*↑.*StartReferences*;
repeat *ReadWord*; ⟨ Parse single reference 1792 ⟩;
until *CurWord.Kind* ≠ *sy_Comma*;
gItemPtr↑.*FinishReferences*;
end;

See also sections 1796 and 1800.

This code is used in section 1673.

1792. ⟨ Parse single reference 1792 ⟩ ≡
case *CurWord.Kind* **of**
MMLIdentifier: ⟨ Parse library references 1794 ⟩;
Identifier: **begin** *gItemPtr*↑.*ProcessPrivateReference*; *ReadWord* **end**;
othercases *WrongWord* (*paWrongReferenceBeg*);
endcases

This code is used in section 1791.

1793. ⟨ Error codes for parser 1675 ⟩ +≡
paWrongReferenceBeg = 308;

1794. Mizar supports multiple references from the same article to “piggyback” off the same article “anchor”. For example, “GROUP_1:13,def 3,17” refers to theorems 13 and 17 and definition 3 from the MML Article GROUP_1.

If the user forgot to include the theorem or definition number — so they just wrote “⟨Article⟩” instead of “⟨Article⟩:⟨Number⟩” or “⟨Article⟩:def ⟨Number⟩” — then Mizar flags this with a 384 error.

define *no_longer_referencing_article* ≡ (*CurWord.Kind* ≠ *sy_Comma*) ∨
 (*AheadWord.Kind* = *Identifier*) ∨ (*AheadWord.Kind* = *MMLIdentifier*)
 ⟨ Parse library references 1794 ⟩ ≡
begin *gItemPtr*↑.*StartLibraryReferences*; *ReadWord*;
if *CurWord.Kind* = *sy_Colon* **then**
repeat *ReadWord*; *gItemPtr*↑.*ProcessDef*;
if *CurWord.Kind* = *ReferenceSort* **then**
begin if *CurWord.Nr* ≠ *ord*(*syDef*) **then** *ErrImm*(*paDefExp*);
ReadWord;
end;
gItemPtr↑.*ProcessTheoremNumber*; *Accept*(*Numeral*, *paNumExp*);
until *no_longer_referencing_article*
else *MissingWord* (*paColonExp4*);
gItemPtr↑.*FinishTheLibraryReferences*;
end

This code is used in section 1792.

1795. ⟨ Error codes for parser 1675 ⟩ +≡
paNumExp = 307; *paDefExp* = 312; *paColonExp4* = 384;

1796. The Parser is currently looking at “**from**”, which means a reference to a scheme identifier will be given next (possibly followed with a comma-separated list of references in parentheses).

If the user tries to give something else (instead of an identifier of a scheme), then a 308 error will be raised. Also, if the user forgot the closing parentheses around the references for the scheme (e.g., “**from** **MyScheme**(**A1**,**A2**)”), then 370 error will be raised.

```

⟨ Parse simple justifications (parser.pas) 1791 ⟩ +≡
procedure GetSchemeReference;
  begin gItemPtr↑.StartSchemeReference; ReadWord;
  case CurWord.Kind of
    MMLIdentifier: ⟨ Parse reference to scheme from MML 1798 ⟩;
    Identifier: begin gItemPtr↑.ProcessSchemeReference; ReadWord end;
    othercases WrongWord(paWrongReferenceBeg);
  endcases;
  if CurWord.Kind = sy_LeftParanthesis then
    begin GetReferences; Accept(sy_RightParanthesis, paRightParenthExp7)
    end;
  gItemPtr↑.FinishSchemeReference;
end;

```

1797. ⟨ Error codes for parser 1675 ⟩ +≡
paRightParenthExp7 = 370;

1798. Mizar expects scheme references to the MML to be of the form “**from** ⟨*Article*⟩:**sch** ⟨*Number*⟩”. If the user forgot the “**sch**” (after the colon), a 313 error will be raised. If the user supplies something other than a *number* for the scheme, a 307 error will be raised.

```

⟨ Parse reference to scheme from MML 1798 ⟩ ≡
  begin gItemPtr↑.StartSchemeLibraryReference; ReadWord;
  if CurWord.Kind = sy_Colon then
    begin ReadWord; gItemPtr↑.ProcessSch;
    if CurWord.Kind = ReferenceSort then
      begin if CurWord.Nr ≠ ord(sy_Sch) then ErrImm(paSchExp);
      ReadWord;
      end
    else ErrImm(paSchExp);
    gItemPtr↑.ProcessSchemeNumber; Accept(Numeral, paNumExp);
    end
  else MissingWord(paColonExp4);
  gItemPtr↑.FinishSchLibraryReferences;
end

```

This code is used in section 1796.

1799. ⟨ Error codes for parser 1675 ⟩ +≡
paSchExp = 313;

1800. The Parser expects a simple justification — i.e., either a “**by**” followed by some references, or “**from**” followed by a scheme reference. For some “obvious” inferences, no justification may be needed.

⟨ Parse simple justifications (`parser.pas`) 1791 ⟩ +≡

```
procedure SimpleJustification;
  begin gItemPtr↑.StartSimpleJustification;
  case CurWord.Kind of
    sy_By: GetReferences;
    sy_Semicolon, sy_DotEquals: ;
    sy_From: GetSchemeReference;
  othercases WrongWord(paWrongJustificationBeg);
  endcases; gItemPtr↑.FinishSimpleJustification;
end;
```

1801. ⟨ Error codes for parser 1675 ⟩ +≡

paWrongJustificationBeg = 395;

Section 24.5. STATEMENTS AND REASONINGS

1802. Pragmas have been enabled which tells Mizar to skip the proof. The Parser simply stores a counter (initialized to 1), and increments it every time a “**proof**” token has been encountered, but decrements it every time an “**end**” token has been encountered. When the counter has reached zero, the proof has ended, and the Parser can stop skipping things.

There are, of course, other blocks which use “**end**” to terminate it. For example, definitions. But if the Parser should encounter such tokens, then things have gone so horribly awry, the Parser should just quit here and now.

```

⟨ Parse statements and reasoning (parser.pas) 1802 ⟩ ≡
  { Statements & Reasonings }
procedure Reasoning; forward;
procedure IgnoreProof;
  var lCounter: integer; ReasPos: Position;
  begin gBlockPtr↑.StartAtSignProof; ReasPos ← CurPos; ReadTokenProc; lCounter ← 1;
  repeat case CurWord.Kind of
    sy_Proof, sy_Now, sy_Hereby, sy_Case, sy_Suppose: inc(lCounter);
    sy_End: dec(lCounter);
    sy_Reserve, sy_Scheme, sy_Theorem, sy_Definition, sy_Begin, sy_Notation, sy_Registration, EOT: begin
      AcceptEnd(ReasPos); exit
    end;
  endcases; ReadTokenProc;
  until lCounter = 0;
  gBlockPtr↑.FinishAtSignProof;
end;

```

See also sections [1803](#), [1804](#), [1805](#), [1815](#), [1816](#), [1821](#), [1830](#), and [1832](#).

This code is used in section [1673](#).

1803. Parsing either a “**by**” justification (or a “**from**” justification) or a nested “**proof**” block. If the Parser is looking at neither situation, the *SimpleJustification* procedure will raise errors.

```

define parse_proof ≡
  if ProofPragma then Reasoning
  else IgnoreProof
  end;
⟨ Parse statements and reasoning (parser.pas) 1802 ⟩ +≡
procedure Justification;
  begin gItemPtr↑.StartJustification;
  case CurWord.Kind of
    sy_Proof: parse_proof;
  othercases SimpleJustification;
  endcases; gItemPtr↑.FinishJustification;
end;

```

1804. For private predicates (“**defpred**”) and private functors (“**deffunc**”), there will be a list of comma-separated types for the arguments of the private definition.

```

define parse_comma_separated_types ≡
  repeat TypeExpression; gItemPtr↑.FinishLocusType
  until ¬Occurs(sy_Comma)
⟨ Parse statements and reasoning (parser.pas) 1802 ⟩ +≡
procedure ReadTypeList;
begin case CurWord.Kind of
  sy_RightSquareBracket, sy_RightParanthesis: ;
othercases parse_comma_separated_types;
endcases;
end;

```

1805. A “**Private Item**” is a statement (“item”) which introduces a new constant local (“private”) to the block or article.

```

define other_regular_statements ≡ Identifier, sy_Now, sy_For, sy_Ex, sy_Not, sy_Thesis,

end

This code is used in section 1805.

1814. \langle Error codes for parser 1675 $\rangle + \equiv$
 $paIdentExp9 = 300; paAsExp = 388;$

1815. The *SetParserPragma* toggles the state variables for skipping proofs, and storing the pragma in the AST is handled by the *gBlockPtr*’s method call.

\langle Parse statements and reasoning (parser.pas) 1802 $\rangle + \equiv$

procedure *ProcessPragmas*;
begin while $CurWord.Kind = Pragma$ **do**
 $begin SetParserPragma(CurWord.Spelling); \{ (\S 1375) \}$
 $gBlockPtr \uparrow. ProcessPragma; \{ (\S 1395) \}$
 $ReadTokenProc;$
end;
end;

1816. Reasoning items. The “linear reasoning” portion of the Parser corresponds to what “Mizar in a Nutshell” refers to as a sequence of “Reasoning Items”. Basically, everything exception “**per cases**”.

\langle Parse statements and reasoning (`parser.pas`) 1802 $\rangle + \equiv$

procedure *LinearReasoning*;

begin while *CurWord.Kind* \neq *sy_End* **do**

begin *StillCorrect* \leftarrow *true*; *ProcessPragmas*; \langle Parse statement of linear reasoning 1817 \rangle ;
Semicolon;

end;

end;

1817. Most statements are delegated to their own dedicated function.

\langle Parse statement of linear reasoning 1817 $\rangle \equiv$

case *CurWord.Kind* **of**

sy_Let: **begin** *gBlockPtr* \uparrow .*CreateItem(itGeneralization)*; *Generalization*; **end**;

sy_Given: *ExistentialAssumption*;

sy_Assume: **begin** *gBlockPtr* \uparrow .*CreateItem(itAssumption)*; *ReadWord*; *Assumption*; **end**;

sy_Take: \langle Parse “take” statement for linear reasoning 1818 \rangle ;

sy_Hereby: **begin** *gBlockPtr* \uparrow .*CreateItem(itConclusion)*; *Reasoning*; **end**;

\langle Parse “thus” and “hence” for linear reasoning 1819 \rangle ;

sy_Per: *exit*;

sy_Case, *sy_Suppose*: *exit*;

sy_Reserve, *sy_Scheme*, *sy_Theorem*, *sy_Definition*, *sy_Begin*, *sy_Notation*, *sy_Registration*, *EOT*: *exit*;

sy_Then: \langle Parse “then” for linear reasoning 1820 \rangle ;

othercases *PrivateItem*;

endcases

This code is used in section 1816.

1818. Take statements. We recall the syntax for a “take” statement:

$$\text{take } (\langle \text{Term} \rangle \mid \langle \text{Variable} \rangle = \langle \text{Term} \rangle) \{ ", " (\langle \text{Term} \rangle \mid \langle \text{Variable} \rangle = \langle \text{Term} \rangle) \}$$

That is, a comma-separated list of either (1) terms, or (2) a variable equal to a term.

\langle Parse “take” statement for linear reasoning 1818 $\rangle \equiv$

begin *gBlockPtr* \uparrow .*CreateItem(itExemplification)*; *ReadWord*;

repeat if (*CurWord.Kind* = *Identifier*) \wedge (*AheadWord.Kind* = *sy_Equal*) **then**

begin *gItemPtr* \uparrow .*ProcessExemplifyingVariable*; *ReadWord*; *ReadWord*; *TermExpression*;

gItemPtr \uparrow .*FinishExemplifyingVariable*;

end

else begin *gItemPtr* \uparrow .*StartExemplifyingTerm*; *TermExpression*; *gItemPtr* \uparrow .*FinishExemplifyingTerm*;

end;

until \neg *Occurs*(*sy_Comma*);

end

This code is used in section 1817.

1819. Thus statements. Both “**thus**” and “**hence**” (which is syntactic sugar for “**then thus**”) are parsed similarly. So it bears studying them in parallel. The “heavy lifting” is handled by the *RegularStatement* for parsing the formula. But the *gBlockPtr* state variable “primes the pump” by creating a “conclusion” statement.

```

⟨ Parse “thus” and “hence” for linear reasoning 1819 ⟩ ≡
sy_Hence: begin gBlockPtr↑.ProcessLink; ReadWord; gBlockPtr↑.CreateItem(itConclusion);
  RegularStatement;
end;
sy_Thus: begin ReadWord; gBlockPtr↑.ProcessLink;
  if CurWord.Kind = sy_Then then ReadWord;
  gBlockPtr↑.CreateItem(itConclusion); RegularStatement;
end

```

This code is used in section 1817.

1820. Parsing ‘then’ linked statements.

```

⟨ Parse “then” for linear reasoning 1820 ⟩ ≡
begin if AheadWord.Kind = sy_Per then
  begin gBlockPtr↑.ProcessLink; ReadWord; exit; end
else PrivateItem;
end

```

This code is used in section 1817.

1821. Non-block Reasoning. The Parser has just encountered a “**per cases**” statement. Now it must parse “**suppose**” items.

```

⟨ Parse statements and reasoning (parser.pas) 1802 ⟩ +≡
procedure NonBlockReasoning;
  var CasePos: Position; lCaseKind: TokenKind; ⟨ Process “case” (local procedure) 1822 ⟩;
  begin case CurWord.Kind of
    sy_Per, sy_Case, sy_Suppose: begin gBlockPtr↑.CreateItem(itPerCases);
      ⟨ Consume “per cases”, raise an error if they’re missing 1823 ⟩;
      if (CurWord.Kind ≠ sy_Case) ∧ (CurWord.Kind ≠ sy_Suppose) then
        ⟨ Try to synchronize after failing to find initial ‘case’ or ‘suppose’ 1825 ⟩;
      repeat ⟨ Parse “suppose” or “case” block 1827 ⟩;
      until (Curword.Kind = sy_End);
    end;
  endcases;
end;

```

1822. Each “**case**” or “**suppose**” block consists of zero or more linear reasoning items, followed possibly by an optional “non-block reasoning” proof (i.e., another nested “**per cases**” proof by cases).

```

⟨ Process “case” (local procedure) 1822 ⟩ ≡
procedure ProcessCase;
  begin Assumption; Semicolon; LinearReasoning;
  if CurWord.Kind = sy_Per then NonBlockReasoning;
  KillBlock; AcceptEnd(CasePos); Semicolon;
end

```

This code is used in section 1821.

1823. The Parser looks for “per cases” tokens, and some simple justification for the statement. If “per” is missing, a 231 error is raised. If the “cases” is missing, a 351 error is raised. When this code chunk is done, the Parser is looking at either a “suppose” token or a “case” token.

```

⟨ Consume “per cases”, raise an error if they’re missing 1823 ⟩ ≡
  Accept(sy_Per, paPerExp); Accept(sy_Cases, paCasesExp); SimpleJustification; Semicolon;
  lCaseKind ← CurWord.Kind

```

This code is used in section 1821.

1824. ⟨ Error codes for parser 1675 ⟩ +≡
paPerExp = 231; *paCasesExp* = 351;

1825. The Parser is expecting “suppose” or “case” after the “per cases” statement. But if the Parser fails to find either of these tokens, it *should* enter panic mode.

Like a person falling off a cliff reaches out for something to grab, the Parser in panic mode seeks something to “grab on to” so the Parser can “soldier on”. The technical term for this situation is that the Parser is trying to “synchronize” (usually people just talk about “synchronization”).

Mizar raises a 232 error.

```

⟨ Try to synchronize after failing to find initial ‘case’ or ‘suppose’ 1825 ⟩ ≡
  begin MissingWord(paSupposeOrCaseExp); lCaseKind ← sy_Suppose;
  gBlockPtr↑.CreateItem(itCaseBlock); gBlockPtr↑.CreateBlock(blSuppose);
  gBlockPtr↑.CreateItem(itSupposeHead); StillCorrect ← true; CasePos ← CurPos; ProcessCase;
  end

```

This code is used in section 1821.

1826. ⟨ Error codes for parser 1675 ⟩ +≡
paSupposeOrCaseExp = 232;

```

1827. ⟨ Parse “suppose” or “case” block 1827 ⟩ ≡
  while (CurWord.Kind = sy_Case) ∨ (CurWord.Kind = sy_Suppose) do
    ⟨ Parse contents of “suppose” block 1828 ⟩;
  case Curword.Kind of
    sy_Reserve, sy_Scheme, sy_Theorem, sy_Definition, sy_Begin, sy_Notation, sy_Registration, EOT: exit;
    sy_End: ;
  othercases ⟨ Synchronize after missing ‘suppose’ or ‘case’ token 1829 ⟩;
  endcases

```

This code is used in section 1821.

1828. Parsing the contents of a “suppose” or “case” block requires creating a new block (for the, you know, block) and creating a new item for the “suppose $\langle Formula \rangle$ ” or “case $\langle Formula \rangle$ ” statement.

If the user tries to “mix and match” the different kind of suppositions (i.e., “case” and “suppose”), then a 58 error should be raised.

```
define create_supposition_block  $\equiv$ 
    if lCaseKind = sy_Case then gBlockPtr↑.CreateBlock(blCase)
    else gBlockPtr↑.CreateBlock(blSuppose)
define create_supposition_head  $\equiv$ 
    if lCaseKind = sy_Case then gBlockPtr↑.CreateItem(itCaseHead)
    else gBlockPtr↑.CreateItem(itSupposeHead)
```

\langle Parse contents of “suppose” block 1828 $\rangle \equiv$

```
begin gBlockPtr↑.CreateItem(itCaseBlock); create_supposition_block; CasePos  $\leftarrow$  CurPos;
    StillCorrect  $\leftarrow$  true; create_supposition_head;
if CurWord.Kind  $\neq$  lCaseKind then ErrImm(58);
    ReadWord; ProcessCase;
end
```

This code is used in section 1827.

1829. \langle Synchronize after missing ‘suppose’ or ‘case’ token 1829 $\rangle \equiv$

```
begin MissingWord(paSupposeOrCaseExp); gBlockPtr↑.CreateItem(itCaseBlock);
    create_supposition_block; create_supposition_head; StillCorrect  $\leftarrow$  true; CasePos  $\leftarrow$  CurPos;
    ProcessCase;
end
```

This code is used in section 1827.

1830. Reasoning. The Parser is looking at “proof”, “hereby”, or “now”. The syntax for Mizar says that we should expect linear reasoning statements, followed by non-block reasoning (i.e., at most one “per cases” statement, and then “suppose” or “case” blocks).

\langle Parse statements and reasoning (*parser.pas*) 1802 $\rangle + \equiv$

```
procedure Reasoning;
    var ReasPos: Position;
    begin ReasPos  $\leftarrow$  CurPos;
    case CurWord.Kind of
        sy_Proof: begin gBlockPtr↑.CreateBlock(blProof); ReadTokenProc; end;
        sy_Hereby: begin gBlockPtr↑.CreateBlock(blHereby); ReadTokenProc; end;
        sy_Now: begin gBlockPtr↑.CreateBlock(blDiffuse); ReadTokenProc; end;
        othercases begin gBlockPtr↑.CreateBlock(blProof); WrongWord(paProofExp);
            end;
    endcases;
    LinearReasoning; NonBlockReasoning; KillBlock; AcceptEnd(ReasPos);
end;
```

1831. \langle Error codes for parser 1675 $\rangle + \equiv$

```
paProofExp = 389;
```

1832. Regular statements. A regular statement is one of the following:

- (1) “**now**” followed by reasoning;
- (2) A sentence (i.e., possibly labeled formula) followed by a “**proof**” block;
- (3) Iterative equalities.

⟨ Parse statements and reasoning (`parser.pas`) 1802 ⟩ +≡

```

procedure RegularStatement;
  begin ProcessLab; gItemPtr↑.StartRegularStatement;
  case CurWord.Kind of
    sy_Now: Reasoning;
  othercases begin ProcessSentence;
    case CurWord.Kind of
      sy_Proof: ⟨ Parse “proof” block 1833 ⟩;
    othercases begin gItemPtr↑.StartJustification; SimpleJustification; gItemPtr↑.FinishJustification;
      gItemPtr↑.FinishCompactStatement;
      while CurWord.Kind = sy_DotEquals do ⟨ Parse iterative equations 1834 ⟩;
      end;
    endcases;
  end;
endcases;
end;

```

1833. ⟨ Parse “proof” block 1833 ⟩ ≡

```

begin gItemPtr↑.StartJustification;
if ProofPragma then Reasoning
else IgnoreProof;
gItemPtr↑.FinishJustification;
end

```

This code is used in section 1832.

1834. ⟨ Parse iterative equations 1834 ⟩ ≡

```

begin gItemPtr↑.StartIterativeStep; ReadWord; TermExpression; gItemPtr↑.ProcessIterativeStep;
gItemPtr↑.StartJustification; SimpleJustification; gItemPtr↑.FinishJustification;
gItemPtr↑.FinishIterativeStep;
end

```

This code is used in section 1832.

Section 24.6. PATTERNS

1835. Visible arguments (compared to “hidden arguments”) appear to the left or right of a functor or predicate (or to the left of an attribute, or to the right of a mode or structure). The *gVisibleNbr* state variable is initialized to zero when the Parser starts parsing visible arguments, and the Parser increments it for each visible argument in the pattern.

If a non-identifier appears in a pattern, Mizar raises a 300 error. So you cannot be clever and try to trick Mizar into thinking “0 + x” is a pattern.

```

⟨ Parse patterns (parser.pas) 1835 ⟩ ≡
  { Patterns }
var gVisibleNbr: integer;
procedure GetVisible;
begin gItemPtr↑.ProcessVisible; { (§1505) }
  inc(gVisibleNbr); Accept(Identifier, paIdentExp3);
end;

```

See also sections 1837, 1838, 1843, 1845, 1847, 1853, 1856, and 1858.

This code is used in section 1673.

1836. ⟨ Error codes for parser 1675 ⟩ +≡
paIdentExp3 = 300;

1837. We will need to Parse a comma-separated list of identifiers when determining a pattern.

```

⟨ Parse patterns (parser.pas) 1835 ⟩ +≡
procedure ReadVisible;
begin gItemPtr↑.StartVisible; gVisibleNbr ← 0;
repeat GetVisible;
until ¬Occurs(sy_Comma);
  gItemPtr↑.FinishVisible;
end;

```

1838. There are two cases to consider when determining the pattern for a mode: either the Parser is looking at “set” as a type, or—the more interesting case—the Parser is looking at an identifier which appears in a vocabulary file as a mode symbol.

```

⟨ Parse patterns (parser.pas) 1835 ⟩ +≡
procedure GetModePattern;
  var lModesymbol: integer;
begin gItemPtr↑.StartModePattern; { (§1493) }
case CurWord.Kind of
  sy_Set: ⟨ Parse pattern for “set” as a mode 1840 ⟩;
  ModeSymbol: ⟨ Parse pattern for a mode symbols 1842 ⟩
othercases WrongWord(paWrongModePatternBeg);
endcases;
  gItemPtr↑.FinishModePattern; { (§1494) }
end;

```

1839. ⟨ Error codes for parser 1675 ⟩ +≡
paWrongModePatternBeg = 303;

1840. \langle Parse pattern for “set” as a mode 1840 $\rangle \equiv$
begin if *AheadWord.Kind* = *sy_Of* **then** *WrongWord*(*paWrongModePatternSet*)
else *ReadWord*;
end

This code is used in section 1838.

1841. \langle Error codes for parser 1675 $\rangle + \equiv$
paWrongModePatternSet = 315;

1842. The “ \langle Kind \rangle MaxArgs” entry is initialized to \$FF before *ReadVisible* is invoked, which is PASCAL for #FF = 255. So if the *ModeMaxArgs* entry for the mode symbol is (1) less than the number of arguments parsed, or (2) uninitialized; then we should update its entry with the *gVisibleNbr* state variable’s current value.

define *get_index_compare_to_default*(#) \equiv [#] = \$FF
define *entry_is_uninitialized*(#) \equiv #.fList↑*get_index_compare_to_default*
 \langle Parse pattern for a mode symbols 1842 $\rangle \equiv$
begin *lModeSymbol* \leftarrow *CurWord.Nr*; *gVisibleNbr* \leftarrow 0; *ReadWord*; *gItemPtr*↑.*ProcessModePattern*;
if *Occurs*(*sy_Of*) **then** *ReadVisible*;
if (*ModeMaxArgs.fList*↑[*lModeSymbol*] < *gVisibleNbr*) \vee
(*entry_is_uninitialized*(*ModeMaxArgs*)(*lModeSymbol*)) **then**
ModeMaxArgs.fList↑[*lModeSymbol*] \leftarrow *gVisibleNbr*;
end

This code is used in section 1838.

1843. Parsing the visible arguments for a functor relies on this helper function.

\langle Parse patterns (parser.pas) 1835 $\rangle + \equiv$
procedure *ReadParams*;
begin if *Occurs*(*sy_LeftParanthesis*) **then**
begin *ReadVisible*; *Accept*(*sy_RightParanthesis*, *paRightParenthExp5*)
end
else if *CurWord.Kind* = *Identifier* **then**
begin *gItemPtr*↑.*StartVisible*; *GetVisible*; *gItemPtr*↑.*FinishVisible*; **end**;
end;

1844. \langle Error codes for parser 1675 $\rangle + \equiv$
paRightParenthExp5 = 370;

1845. Attribute patterns allows for arguments *only on the right* of the attribute symbol, i.e., something like

$$\text{attr } \underbrace{\langle \text{Identifier} \rangle \text{ is } \langle \text{Arguments} \rangle \langle \text{Attribute-Name} \rangle}_{\text{pattern}} \text{ means } \dots$$

⟨ Parse patterns (parser.pas) 1835 ⟩ +≡

```

procedure GetAttrPattern;
  begin gItemPtr↑.StartAttributePattern; gVisibleNbr ← 0; GetVisible;
  gItemPtr↑.ProcessAttributePattern; Accept(sy_Is, paIsExp);
  if Occurs(sy_LeftParanthesis) then
    begin ReadVisible; Accept(sy_RightParanthesis, paRightParenthExp11)
    end
  else if CurWord.Kind = Identifier then ReadVisible;
  gItemPtr↑.FinishAttributePattern; Accept(AttributeSymbol, paAttrExp2);
  end;

```

1846. ⟨ Error codes for parser 1675 ⟩ +≡

paAttrExp2 = 306; paRightParenthExp11 = 370; paIsExp = 383;

1847. Functor patterns generically look like:

$$\text{func } \underbrace{\langle \text{Arguments} \rangle \langle \text{Identifier} \rangle \langle \text{Arguments} \rangle}_{\text{pattern}} \rightarrow \dots$$

or

$$\text{func } \underbrace{\langle \text{Left-Bracket} \rangle \langle \text{Arguments} \rangle \langle \text{Right-Bracket} \rangle}_{\text{pattern}} \rightarrow \dots$$

⟨ Parse patterns (parser.pas) 1835 ⟩ +≡

```

procedure GetFuncPattern;
  begin gItemPtr↑.StartFunctorPattern;
  case CurWord.Kind of
    Identifier, InfixOperatorSymbol, sy_LeftParanthesis: ⟨ Parse infix functor pattern 1849 ⟩;
    LeftCircumfixSymbol, sy_LeftSquareBracket, sy_LeftCurlyBracket: ⟨ Parse bracket functor pattern 1851 ⟩;
    othercases begin WrongWord(paWrongFunctorPatternBeg); gItemPtr↑.FinishFunctorPattern; end;
  endcases;
  end;

```

1848. ⟨ Error codes for parser 1675 ⟩ +≡

paWrongFunctorPatternBeg = 399;

1849. ⟨ Parse infix functor pattern 1849 ⟩ ≡

```

begin ReadParams; gItemPtr↑.ProcessFunctorSymbol; { (§1502) }
  Accept(InfixOperatorSymbol, paFuncExp2); ReadParams; gItemPtr↑.FinishFunctorPattern;
end

```

This code is used in section 1847.

1850. ⟨ Error codes for parser 1675 ⟩ +≡

paFuncExp2 = 302;

1851. \langle Parse bracket functor pattern 1851 $\rangle \equiv$
begin *ReadWord*; *ReadVisible*; *gItemPtr*↑.*FinishFunctorPattern*;
case *Curword.Kind* **of**
sy_RightSquareBracket, *sy_RightCurlyBracket*, *sy_RightParanthesis*: *ReadWord*;
othercases *Accept*(*RightCircumfixSymbol*, *paRightBraExp2*);
endcases;
end

This code is used in section 1847.

1852. \langle Error codes for parser 1675 $\rangle + \equiv$
paRightBraExp2 = 310;

1853. Predicate patterns resemble infix functor patterns.

\langle Parse patterns (*parser.pas*) 1835 $\rangle + \equiv$
procedure *GetPredPattern*;
var *lPredSymbol*: *integer*;
begin *gItemPtr*↑.*StartPredicatePattern*;
if *CurWord.Kind* = *Identifier* **then** *ReadVisible*;
gItemPtr↑.*ProcessPredicateSymbol*;
case *CurWord.Kind* **of**
sy_Equal, *PredicateSymbol*: \langle Parse predicate pattern 1855 \rangle ;
othercases *WrongWord*(*paWrongPredPattern*);
endcases; *gItemPtr*↑.*FinishPredicatePattern*;
end;

1854. \langle Error codes for parser 1675 $\rangle + \equiv$
paWrongPredPattern = 301;

1855. \langle Parse predicate pattern 1855 $\rangle \equiv$
begin *lPredSymbol* \leftarrow *CurWord.Nr*;
if *CurWord.Kind* = *sy_Equal* **then** *lPredSymbol* \leftarrow *EqualitySym*;
gVisibleNbr \leftarrow 0; *ReadWord*;
if *CurWord.Kind* = *Identifier* **then** *ReadVisible*;
if (*PredMaxArgs.fList*↑[*lPredSymbol*] < *gVisibleNbr*) \vee (*entry_is_uninitialized*(*PredMaxArgs*)(*lPredSymbol*))
then *PredMaxArgs.fList*↑[*lPredSymbol*] \leftarrow *gVisibleNbr*;
end

This code is used in section 1853.

1856. The “specification” (appearing in a non-expandable mode and functor definitions) refers to the “ \rightarrow *Type*” portion which gives the type for the functor or mode.

\langle Parse patterns (*parser.pas*) 1835 $\rangle + \equiv$
procedure *Specification*;
begin *gItemPtr*↑.*StartSpecification*; *Accept*(*sy_Arrow*, *paArrowExp1*); *TypeExpression*;
gItemPtr↑.*FinishSpecification*;
end;

1857. \langle Error codes for parser 1675 $\rangle + \equiv$
paArrowExp1 = 385;

1858. Parsing a structure pattern is a bit misleading. Unlike the previous procedures, this will actually parse the entirety of a structure definition:

struct $\langle Identifier \rangle$ ($\langle Types \rangle$) (# $\langle Fields \rangle$ #)

\langle Parse patterns (parser.pas) 1835 $\rangle + \equiv$

procedure *GetStructPatterns*;

var *lStructureSymbol*: integer;

begin *gBlockPtr*↑.CreateItem(*itDefStruct*); ReadWord;

\langle Parse ancestors of structure, if there are any 1859 \rangle ;

\langle Parse “over” and any structure arguments, if any 1861 \rangle ;

gItemPtr↑.StartFields;

\langle Update max arguments for structure symbol, if needed 1863 \rangle ;

\langle Parse the fields of the structure definition 1864 \rangle ;

end;

1859. \langle Parse ancestors of structure, if there are any 1859 $\rangle \equiv$

if *CurWord.Kind* = *sy_LeftParanthesis* **then**

begin repeat *gItemPtr*↑.StartPrefix; ReadWord; TypeExpression; *gItemPtr*↑.FinishPrefix;

until *CurWord.Kind* \neq *sy_Comma*;

 Accept(*sy_RightParanthesis*, *paRightParenthExp6*);

end

This code is used in section 1858.

1860. \langle Error codes for parser 1675 $\rangle + \equiv$

paRightParenthExp6 = 370;

1861. \langle Parse “over” and any structure arguments, if any 1861 $\rangle \equiv$

gItemPtr↑.ProcessStructureSymbol; *lStructureSymbol* \leftarrow \$FF;

if *CurWord.Kind* = *StructureSymbol* **then** *lStructureSymbol* \leftarrow *CurWord.Nr*;

 Accept(*StructureSymbol*, *paStructExp1*);

if Occurs(*sy_Over*) **then** ReadVisible

This code is used in section 1858.

1862. \langle Error codes for parser 1675 $\rangle + \equiv$

paStructExp1 = 304;

1863. \langle Update max arguments for structure symbol, if needed 1863 $\rangle \equiv$

if *lStructureSymbol* \neq \$FF **then**

if (*StructModeMaxArgs.fList*↑[*lStructureSymbol*] < *gVisibleNbr*) \vee

 (*entry_is_uninitialized*(*StructModeMaxArgs*)(*lStructureSymbol*)) **then**

StructModeMaxArgs.fList↑[*lStructureSymbol*] \leftarrow *gVisibleNbr*

This code is used in section 1858.

1864. \langle Parse the fields of the structure definition 1864 $\rangle \equiv$

 Accept(*sy_StructLeftBracket*, *paLeftDoubleExp3*);

repeat \langle Parse field for the structure definition 1866 \rangle ;

until \neg Occurs(*sy_Comma*);

gItemPtr↑.FinishFields; Accept(*sy_StructRightBracket*, *paRightDoubleExp2*)

This code is used in section 1858.

1865. \langle Error codes for parser 1675 $\rangle + \equiv$
paLeftDoubleExp3 = 363; *paRightDoubleExp2* = 373;

1866. \langle Parse field for the structure definition 1866 $\rangle \equiv$
gItemPtr↑.*StartAggrPattSegment*;
repeat *gItemPtr*↑.*ProcessField*; *Accept*(*SelectorSymbol*, *paSelectExp1*);
until \neg *Occurs*(*sy_Comma*);
Specification; *gItemPtr*↑.*FinishAggrPattSegment*

This code is used in section 1864.

1867. \langle Error codes for parser 1675 $\rangle + \equiv$

  end

```

This code is used in section 1915.

Section 24.9. MAIN PARSE PROCEDURE

1921. The main *Parse* method essentially skips ahead to the first “**begin**”, then skips ahead to the first top-level block statement.

```

define skip_to_begin  $\equiv$  ReadTokenProc;
      while (CurWord.Kind  $\neq$  sy_Begin)  $\wedge$  (CurWord.Kind  $\neq$  EOT) do ReadTokenProc
 $\langle$  Main parse method (parser.pas) 1921  $\rangle \equiv$ 
procedure Parse;
  begin skip_to_begin; { Skips ahead until EOT or finds ‘begin’ }
  if CurWord.Kind = EOT then ErrImm(213)
  else  $\langle$  Parse proper text 1922  $\rangle$ ; { CurWord.Kind = sy_Begin }
  KillBlock;
end;

```

This code is used in section 1673.

1922. Parsing the “text proper” checks that we have encountered a “**begin**” keyword, then parses the block statements in the article’s contents.

Note that *ProcessBegin* (§1394) and *StartProperText* (§1396) are both implemented in the extended block class.

```

[[The 213 magic number should be made a constant, something like paBegExpected?]]
 $\langle$  Parse proper text 1922  $\rangle \equiv$ 
  begin gBlockPtr $\uparrow$ .StartProperText; gBlockPtr $\uparrow$ .ProcessBegin; Accept(sy_Begin, 213);
  while CurWord.Kind  $\neq$  EOT do  $\langle$  Parse next block 1923  $\rangle$ ;
end

```

This code is used in section 1921.

1923. When parsing the next top-level block in a Mizar article, we tell Mizar’s Parser we are not in “panic mode”. Then we test for unexpected “end” tokens. If we can recover a “begin” token, just start the loop over again.

If we encounter an “end of text” token, then we should terminate the loop.

Otherwise, we dispatch the Parser’s control depending on the kind of token we encounter.

```

⟨ Parse next block 1923 ⟩ ≡
  begin ⟨ Parse pragmas and begins 1924 ⟩;
  StillCorrect ← true; { we are not in panic mode }
  if CurWord.Kind = sy_End then
    begin ⟨ Skip all end tokens, report errors 1925 ⟩;
    if CurWord.Kind = sy_Begin then continue;
    end;
  if CurWord.Kind = EOT then break;
  case CurWord.Kind of
    sy_Scheme: SchemeBlock;
    sy_Definition: DefinitionalBlock;
    sy_Notation: NotationBlock;
    sy_Registration: RegistrationBlock;
    sy_Reserve: Reservation;
    sy_Theorem: Theorem;
    sy_Axiom: Axiom;
    sy_Canceled: Canceled;
    sy_Case, sy_Suppose, sy_Per, sy_Hereby: UnexpectedItem;
  othercases PrivateItem;
  endcases;
  Semicolon; { block is expected to end in a semicolon }
end

```

This code is used in section 1922.

1924. The *ProcessPragmas* (§1815) consumes a token when the current token is a pragma. So we effectively have a loop where we consume all the pragmas and the “begin” keywords until we find something else.

```

⟨ Parse pragmas and begins 1924 ⟩ ≡
  while CurWord.Kind ∈ [sy_Begin, Pragma] do
    begin ProcessPragmas;
    if CurWord.Kind = sy_Begin then
      begin gBlockPtr↑.ProcessBegin; ReadTokenProc;
      end;
    end
  end

```

This code is used in section 1923.

1925. In the unfortunate event that the Parser has stumbled across an “end” token, skip all the “end” and semicolon tokens and report errors.

```

⟨ Skip all end tokens, report errors 1925 ⟩ ≡
  repeat ErrImm(216); ReadTokenProc;
    if CurWord.Kind = sy_Semicolon then ReadTokenProc;
  until CurWord.Kind ≠ sy_End

```

This code is used in section 1923.

1926. Index. Underlined entries in an index item refers to which section defines the identifier. Primitive types (*char*, *Boolean*, *string*, etc.) are omitted from the index.

- ⟨ Absolute value for an arbitrary-precision number 205 ⟩ Used in section 198.
- ⟨ Abstract base class for formulas 968 ⟩ Used in section 897.
- ⟨ Abstract base class for terms 913 ⟩ Used in section 897.
- ⟨ Abstract base class for types 957 ⟩ Used in section 897.
- ⟨ Abstract vocabulary object declaration 731 ⟩ Used in section 716.
- ⟨ Add $a1$ and $b1$ as in step 1, Eq (211.2) 213 ⟩ Used in section 211.
- ⟨ Add token to tokens buffer and iterate 784 ⟩ Used in section 782.
- ⟨ Add two negative integers, and **goto** *ex* 240 ⟩ Used in section 239.
- ⟨ Adjective (abstract syntax tree) 911 ⟩ Used in section 897.
- ⟨ Adjective AST constructor 912 ⟩ Used in section 896.
- ⟨ Adjective expression (abstract syntax tree) 907 ⟩ Used in section 897.
- ⟨ Adjective expression AST constructor 908 ⟩ Used in section 896.
- ⟨ Aggregate term (abstract syntax tree) 936 ⟩ Used in section 915.
- ⟨ Allocate a new array for *IntPairSeq*, and copy the contents over 493 ⟩ Used in section 492.
- ⟨ Allocate a new array, and copy old contents into new array 345 ⟩ Used in section 343.
- ⟨ Allocate and copy items to new sorted list 396 ⟩ Used in sections 394 and 419.
- ⟨ Append next digit of a onto s , incrementing c 231 ⟩ Used in sections 229 and 229.
- ⟨ Arbitrary-precision rational arithmetic 259, 261, 263, 265, 267, 269, 271, 273, 275 ⟩ Used in section 198.
- ⟨ Arithmetic for arbitrary-precision integers 211, 215, 219, 221, 224, 226, 233, 235, 237, 239, 244, 249, 251, 253, 255 ⟩
Used in section 198.
- ⟨ Assert MML version is compatible with Mizar version 642 ⟩ Used in section 639.
- ⟨ Assert *fCompare* is present 406 ⟩ Used in sections 405 and 426.
- ⟨ Basic arithmetic operations declarations 204, 225, 232, 234, 236, 238, 243, 248, 250, 252, 254 ⟩ Used in section 198.
- ⟨ Block object implementation 854, 855, 856, 857, 858, 859, 860 ⟩ Used in section 843.
- ⟨ Block object interface 853 ⟩ Used in section 848.
- ⟨ BlockKinds (**syntax.pas**) 852 ⟩ Used in section 848.
- ⟨ Calculate $(-a) + b = b - a$ and **goto** *ex* 241 ⟩ Used in section 239.
- ⟨ Calculate $(-a) - (-b)$ and **goto** *ex* 246 ⟩ Used in section 244.
- ⟨ Calculate $(-a) - b = -(a + b)$ and **goto** *ex* 245 ⟩ Used in section 244.
- ⟨ Calculate $a + (-b) = a - b$ and **goto** *ex* 242 ⟩ Used in section 239.
- ⟨ Calculate difference of two positive integers 247 ⟩ Used in section 244.
- ⟨ Calculate quotient for nonzero divisor 297 ⟩ Used in section 296.
- ⟨ Calculate the usual multiplication of complex numbers 294 ⟩ Used in section 293.
- ⟨ Carry the c_{m+1} as in step 2, Eq (211.3) 214 ⟩ Used in section 211.
- ⟨ Characters prohibited by *MScanner* 794 ⟩ Used in section 793.
- ⟨ Check all extendible items have been digested, otherwise raise error 374 ⟩ Used in sections 373, 375, 376, 377, 382, and 416.
- ⟨ Check every remaining open (left) parentheses has a corresponding partner 1719 ⟩ Used in section 1716.
- ⟨ Check for 172/173 error, **goto** *AfterBalance* if erred 1599 ⟩ Used in section 1598.
- ⟨ Check for 174/175 error, **goto** *AfterBalance* if erred 1600 ⟩ Used in section 1598.
- ⟨ Check for errors with definition items 1433 ⟩ Used in section 1429.
- ⟨ Check identifier is not a number 782 ⟩ Used in section 773.
- ⟨ Check if arbitrary-precision integers are zero 201 ⟩ Used in section 198.
- ⟨ Check if functor symbol is valid 720 ⟩ Used in section 718.
- ⟨ Check if predicate symbol is valid 721 ⟩ Used in section 718.
- ⟨ Check term $B1$ has valid functor format, **goto** *AfterBalance* if not 1605 ⟩ Used in section 1604.
- ⟨ Check the popped item's linkages are valid 1456 ⟩ Used in section 1429.
- ⟨ Check we are redefining a mode, attribute, functor, or predicate 1889 ⟩ Used in section 1888.
- ⟨ Check *Index* for *MCollection* is within bounds, raise an error if it's out of bounds 353 ⟩ Used in sections 352, 356, and 359.
- ⟨ Choice term (abstract syntax tree) 950 ⟩ Used in section 915.
- ⟨ Circumfix term (abstract syntax tree) 926 ⟩ Used in section 915.

- ⟨ Class declaration for Item object 863 ⟩ Used in section 848.
- ⟨ Class declarations for `dicthan.pas` 716 ⟩ Used in section 714.
- ⟨ Class for Within expression 1010 ⟩ Used in section 897.
- ⟨ Classes for formula (abstract syntax tree) 970, 972, 974, 976, 978, 980, 982, 984, 986, 988, 990, 992, 994, 996, 998, 1000, 1002, 1004, 1006, 1008 ⟩ Used in section 897.
- ⟨ Classes for terms (abstract syntax tree) 915 ⟩ Used in section 897.
- ⟨ Classes for type (abstract syntax tree) 958, 960, 962, 964, 966 ⟩ Used in section 897.
- ⟨ Close parentheses for formula 1764 ⟩ Used in section 1760.
- ⟨ Close the parentheses 1734 ⟩ Used in section 1727.
- ⟨ Communicate with items (`parser.pas`) 1773 ⟩ Used in section 1673.
- ⟨ Compare bracket symbols 823 ⟩ Used in section 821.
- ⟨ Compare formats 819 ⟩ Used in section 810.
- ⟨ Compare infix symbols 824 ⟩ Used in sections 821 and 823.
- ⟨ Compare prefix symbols 822 ⟩ Used in section 821.
- ⟨ Compare same kind symbols with the same number 821 ⟩ Used in section 820.
- ⟨ Compare symbols of the same kind 820 ⟩ Used in section 819.
- ⟨ Compare two positive integers with same number of digits 207 ⟩ Used in section 206.
- ⟨ Complex-rational arbitrary-precision arithmetic 279, 281, 283, 285, 287, 289, 291, 293, 296, 299, 301, 303, 305 ⟩
Used in section 198.
- ⟨ Constants for `pcmizver.pas` 81, 82, 83 ⟩ Used in section 80.
- ⟨ Constants for `xml_parser.pas` 647 ⟩ Used in section 646.
- ⟨ Constants for common error messages reported to console 124 ⟩ Used in section 89.
- ⟨ Constants of `xml_dict.pas` 614, 616 ⟩ Used in section 612.
- ⟨ Construct the term's syntax tree after balancing arguments among subterms 1607 ⟩ Used in section 1597.
- ⟨ Constructors for derived format classes 812, 814, 816, 818 ⟩ Used in section 810.
- ⟨ Constructors for example statements (`wsmarticle.pas`) 1084 ⟩ Used in section 1081.
- ⟨ Consume “does not” or “do not”, raise error otherwise 1749 ⟩ Used in section 1748.
- ⟨ Consume “per cases”, raise an error if they're missing 1823 ⟩ Used in section 1821.
- ⟨ Convert “-0” into zero 202 ⟩ Used in section 201.
- ⟨ Copy a and b into $a1$, $b1$ ensuring $a1$ is a longer string 212 ⟩ Used in section 211.
- ⟨ Copy a into $a1$ and b into $b1$, ensuring $b1$ is a shorter string 222 ⟩ Used in section 221.
- ⟨ Copy environment variable's value into $lStr$ until we find null character 69 ⟩ Used in section 67.
- ⟨ Copy remainder of a into s , and terminate the function 230 ⟩ Used in section 229.
- ⟨ Copy the variable name as a null-terminated string 68 ⟩ Used in section 67.
- ⟨ Count $lNbr$ the number of dictionary entries for an article 739 ⟩ Used in section 738.
- ⟨ Create a subexpression for an expression 872 ⟩ Used in section 843.
- ⟨ De-duplicate a string list 459 ⟩ Used in section 458.
- ⟨ Declare XML Attribute Object 649 ⟩ Used in section 648.
- ⟨ Declare XML Parser object 661 ⟩ Used in section 648.
- ⟨ Declare XML Scanner Object type 653 ⟩ Used in section 648.
- ⟨ Declare *FileDescrCollection* data type 622 ⟩ Used in section 617.
- ⟨ Declare *FileDescr* data type 619 ⟩ Used in section 617.
- ⟨ Declare *MBracketFormat* object 817 ⟩ Used in section 809.
- ⟨ Declare *MFormatsList* object 825 ⟩ Used in section 809.
- ⟨ Declare *MFormat* object 811 ⟩ Used in section 809.
- ⟨ Declare *MInfixFormat* object 815 ⟩ Used in section 809.
- ⟨ Declare *MPrefixFormat* object 813 ⟩ Used in section 809.
- ⟨ Declare classes for `_formats.pas` 809 ⟩ Used in section 807.
- ⟨ Declare internal methods for *StringList* 453 ⟩ Used in section 452.
- ⟨ Declare public comparison operators for arbitrary-precision numbers 302, 304 ⟩ Used in section 198.
- ⟨ Declare public complex-valued arbitrary precision arithmetic 284, 286, 288, 290, 292, 295, 298, 300 ⟩ Used in section 198.

- ⟨ Declare *Position* as **record** 129 ⟩ Used in section 128.
- ⟨ Delphi declaration of *CtrlSignal* for Windows 166 ⟩ Used in section 164.
- ⟨ Delphi implementation of *InitCtrl* for Windows 163 ⟩ Used in section 161.
- ⟨ Determine the ID 776 ⟩ Used in section 773.
- ⟨ Emit XML for Fraenkel term (WSM) 1233 ⟩ Used in section 1225.
- ⟨ Emit XML for **consider** contents (WSM) 1262 ⟩ Used in section 1260.
- ⟨ Emit XML for **reconsider** contents (WSM) 1263 ⟩ Used in section 1260.
- ⟨ Emit XML for aggregate term (WSM) 1229 ⟩ Used in section 1225.
- ⟨ Emit XML for assumptions item (WSM) 1272 ⟩ Used in section 1264.
- ⟨ Emit XML for attribute pattern (WSM) 1246 ⟩ Used in section 1241.
- ⟨ Emit XML for attributive formula (WSM) 1218 ⟩ Used in section 1207.
- ⟨ Emit XML for biconditional formula (WSM) 1212 ⟩ Used in section 1207.
- ⟨ Emit XML for bracket functor pattern (WSM) 1244 ⟩ Used in section 1241.
- ⟨ Emit XML for circumfix term (WSM) 1228 ⟩ Used in section 1225.
- ⟨ Emit XML for conditional formula (WSM) 1211 ⟩ Used in section 1207.
- ⟨ Emit XML for conjunction (WSM) 1209 ⟩ Used in section 1207.
- ⟨ Emit XML for definition-related items (WSM) 1264, 1265, 1266, 1267, 1268, 1269, 1270, 1271 ⟩ Used in section 1260.
- ⟨ Emit XML for disjunction (WSM) 1210 ⟩ Used in section 1207.
- ⟨ Emit XML for exactly qualification term (WSM) 1236 ⟩ Used in section 1225.
- ⟨ Emit XML for existential formula (WSM) 1221 ⟩ Used in section 1207.
- ⟨ Emit XML for flexary-conjunction (WSM) 1213 ⟩ Used in section 1207.
- ⟨ Emit XML for flexary-disjunction (WSM) 1214 ⟩ Used in section 1207.
- ⟨ Emit XML for forgetful functor (WSM) 1231 ⟩ Used in section 1225.
- ⟨ Emit XML for global choice term (WSM) 1237 ⟩ Used in section 1225.
- ⟨ Emit XML for infix functor pattern (WSM) 1243 ⟩ Used in section 1241.
- ⟨ Emit XML for infix term (WSM) 1227 ⟩ Used in section 1225.
- ⟨ Emit XML for internal forgetful functor (WSM) 1232 ⟩ Used in section 1225.
- ⟨ Emit XML for mode pattern (WSM) 1245 ⟩ Used in section 1241.
- ⟨ Emit XML for multi-predicative formula (WSM) 1217 ⟩ Used in section 1207.
- ⟨ Emit XML for negated formula (WSM) 1208 ⟩ Used in section 1207.
- ⟨ Emit XML for placeholder (WSM) 1226 ⟩ Used in section 1225.
- ⟨ Emit XML for predicate pattern (WSM) 1242 ⟩ Used in section 1241.
- ⟨ Emit XML for predicative formula (WSM) 1215 ⟩ Used in section 1207.
- ⟨ Emit XML for qualification term (WSM) 1235 ⟩ Used in section 1225.
- ⟨ Emit XML for qualifying formula (WSM) 1219 ⟩ Used in section 1207.
- ⟨ Emit XML for registration-related items (WSM) 1273, 1274 ⟩ Used in section 1260.
- ⟨ Emit XML for right-side of predicative formula (WSM) 1216 ⟩ Used in section 1207.
- ⟨ Emit XML for schema (WSM) 1261 ⟩ Used in section 1260.
- ⟨ Emit XML for selector term (WSM) 1230 ⟩ Used in section 1225.
- ⟨ Emit XML for simple Fraenkel term (WSM) 1234 ⟩ Used in section 1225.
- ⟨ Emit XML for universal formula (WSM) 1220 ⟩ Used in section 1207.
- ⟨ Empty method declarations for *SubexpObj* 877 ⟩ Used in section 873.
- ⟨ Ensure $b \leq s$ by adding another digit of a , initialize z 228 ⟩ Used in section 227.
- ⟨ Ensure capacity of *MCollection*, raise *coOverflow* error if $\Delta = 0$ 357 ⟩ Used in section 356.
- ⟨ Ensure $Count \leq ALimit \leq MaxCollectionSize$ 344 ⟩ Used in sections 343 and 419.
- ⟨ Ensure $Count \leq aLimit \leq MaxCollectionSize$ for sorted lists 395 ⟩ Used in section 394.
- ⟨ Ensure $Count + fExtCount \leq ALimit \leq MaxCollectionSize$ 380 ⟩ Used in section 379.
- ⟨ Error codes for parser 1675, 1681, 1694, 1697, 1699, 1701, 1704, 1707, 1710, 1712, 1715, 1717, 1723, 1726, 1728, 1730, 1732, 1741, 1743, 1745, 1750, 1753, 1755, 1759, 1761, 1763, 1765, 1771, 1784, 1786, 1788, 1793, 1795, 1797, 1799, 1801, 1806, 1808, 1810, 1812, 1814, 1824, 1826, 1831, 1836, 1839, 1841, 1844, 1846, 1848, 1850, 1852, 1854, 1857, 1860, 1862, 1864, 1866, 1868, 1870, 1872, 1874, 1876, 1878, 1880, 1882, 1884, 1886, 1888, 1890, 1892, 1894, 1896, 1898, 1900, 1902, 1904, 1906, 1908, 1910, 1912, 1914, 1916, 1918, 1920, 1922, 1924, 1926, 1928, 1930, 1932, 1934, 1936, 1938, 1940, 1942, 1944, 1946, 1948, 1950, 1952, 1954, 1956, 1958, 1960, 1962, 1964, 1966, 1968, 1970, 1972, 1974, 1976, 1978, 1980, 1982, 1984, 1986, 1988, 1990, 1992, 1994, 1996, 1998, 2000, 2002, 2004, 2006, 2008, 2010, 2012, 2014, 2016, 2018, 2020, 2022, 2024, 2026, 2028, 2030, 2032, 2034, 2036, 2038, 2040, 2042, 2044, 2046, 2048, 2050, 2052, 2054, 2056, 2058, 2060, 2062, 2064, 2066, 2068, 2070, 2072, 2074, 2076, 2078, 2080, 2082, 2084, 2086, 2088, 2090, 2092, 2094, 2096, 2098, 2100, 2102, 2104, 2106, 2108, 2110, 2112, 2114, 2116, 2118, 2120, 2122, 2124, 2126, 2128, 2130, 2132, 2134, 2136, 2138, 2140, 2142, 2144, 2146, 2148, 2150, 2152, 2154, 2156, 2158, 2160, 2162, 2164, 2166, 2168, 2170, 2172, 2174, 2176, 2178, 2180, 2182, 2184, 2186, 2188, 2190, 2192, 2194, 2196, 2198, 2200, 2202, 2204, 2206, 2208, 2210, 2212, 2214, 2216, 2218, 2220, 2222, 2224, 2226, 2228, 2230, 2232, 2234, 2236, 2238, 2240, 2242, 2244, 2246, 2248, 2250, 2252, 2254, 2256, 2258, 2260, 2262, 2264, 2266, 2268, 2270, 2272, 2274, 2276, 2278, 2280, 2282, 2284, 2286, 2288, 2290, 2292, 2294, 2296, 2298, 2300, 2302, 2304, 2306, 2308, 2310, 2312, 2314, 2316, 2318, 2320, 2322, 2324, 2326, 2328, 2330, 2332, 2334, 2336, 2338, 2340, 2342, 2344, 2346, 2348, 2350, 2352, 2354, 2356, 2358, 2360, 2362, 2364, 2366, 2368, 2370, 2372, 2374, 2376, 2378, 2380, 2382, 2384, 2386, 2388, 2390, 2392, 2394, 2396, 2398, 2400, 2402, 2404, 2406, 2408, 2410, 2412, 2414, 2416, 2418, 2420, 2422, 2424, 2426, 2428, 2430, 2432, 2434, 2436, 2438, 2440, 2442, 2444, 2446, 2448, 2450, 2452, 2454, 2456, 2458, 2460, 2462, 2464, 2466, 2468, 2470, 2472, 2474, 2476, 2478, 2480, 2482, 2484, 2486, 2488, 2490, 2492, 2494, 2496, 2498, 2500, 2502, 2504, 2506, 2508, 2510, 2512, 2514, 2516, 2518, 2520, 2522, 2524, 2526, 2528, 2530, 2532, 2534, 4912, 4914, 4916, 4918, 4920, 4922, 4924, 4926, 4928, 4930, 4932, 4934, 4936, 4938, 4940, 4942, 4944, 4946, 4948, 4950, 4952, 4954, 4956, 4958, 4960, 4962, 4964, 4966, 4968, 4970, 4972, 4974, 4976, 4978, 4980, 4982, 4984, 4986, 4988, 4990, 4992, 4994, 4996, 4998, 5000, 5002, 5004, 5006, 5008, 5010, 5012, 5014, 5016, 5018, 5020, 5022, 5024, 5026, 5028, 5030, 5032, 5034, 5036, 5038, 5040, 5042, 5044, 5046, 5048, 5050, 5052, 5054, 5056, 5058, 5060, 5062, 5064, 5066, 5068, 5070, 5072, 5074, 5076, 5078, 5080, 5082, 5084, 5086, 5088, 5090, 5092, 5094, 5096, 5098, 5100, 5102, 5104, 5106, 5108, 5110, 5112, 5114, 5116, 5118, 5120, 5122, 5124, 5126, 5128, 5130, 5132, 5134, 5136, 5138, 5140, 5142, 5144, 5146, 5148, 5150, 5152, 5154, 5156, 5158, 5160, 5162, 5164, 5166, 5168, 5170, 5172, 5174, 5176, 5178, 5180, 5182, 5184, 5186, 5188, 5190, 5192, 5194, 5196, 5198, 5200, 5202, 5204, 5206, 5208, 5210, 5212, 5214, 5216, 5218, 5220, 5222, 5224, 5226, 5228, 5230, 5232, 5234, 5236, 5238, 5240, 5242, 5244, 5246, 5248, 5250, 5252, 5254, 5256, 5258, 5260, 5262, 5264, 5266, 5268, 5270, 5272, 5274, 5276, 5278

- 1865, 1867, 1874, 1876, 1878, 1882, 1884, 1886, 1890, 1896, 1899, 1901, 1905, 1907, 1909, 1912, 1916, 1918} Used in section 1674.
- < Exactly term (abstract syntax tree) 948 > Used in section 915.
- < Example classes (**wsmarticle.pas**) 1083 > Used in section 1080.
- < ExpKinds (**syntax.pas**) 869 > Used in section 848.
- < Expression class declaration 870 > Used in section 848.
- < Expression constructor 871 > Used in section 843.
- < Extended block class declaration 1385 > Used in section 1379.
- < Extended block implementation 1386, 1393, 1394, 1395, 1396, 1397, 1398, 1399, 1401, 1402, 1403 > Used in section 1380.
- < Extended expression class declaration 1669 > Used in section 1379.
- < Extended expression implementation 1670, 1671 > Used in section 1380.
- < Extended item class declaration 1405 > Used in section 1379.
- < Extended item implementation 1406, 1429, 1457, 1459, 1460, 1461, 1462, 1463, 1465, 1466, 1468, 1469, 1470, 1471, 1473, 1474, 1475, 1476, 1479, 1480, 1481, 1483, 1484, 1485, 1486, 1487, 1490, 1491, 1492, 1493, 1494, 1495, 1498, 1499, 1501, 1502, 1503, 1504, 1505, 1506, 1507, 1509, 1510, 1512, 1513, 1514, 1515, 1517, 1519, 1521, 1522, 1523, 1524, 1525, 1527, 1529, 1530, 1531, 1532, 1533, 1534, 1535, 1536, 1537, 1538, 1539, 1540, 1541, 1542, 1543, 1544, 1545, 1546, 1548, 1549, 1551, 1552, 1553, 1555, 1556, 1557, 1558, 1559, 1560, 1561, 1563, 1564, 1565 > Used in section 1380.
- < Extended subexpression class declaration 1568 > Used in section 1379.
- < Extended subexpression implementation 1570, 1571, 1572, 1573, 1575, 1576, 1577, 1578, 1579, 1580, 1581, 1582, 1583, 1584, 1585, 1586, 1587, 1588, 1589, 1590, 1591, 1593, 1597, 1609, 1610, 1611, 1612, 1613, 1614, 1615, 1616, 1617, 1618, 1619, 1620, 1621, 1622, 1623, 1624, 1625, 1626, 1627, 1628, 1629, 1630, 1631, 1632, 1633, 1634, 1635, 1636, 1637, 1638, 1639, 1640, 1641, 1642, 1643, 1644, 1645, 1646, 1647, 1648, 1649, 1650, 1651, 1652, 1653, 1654, 1655, 1656, 1657, 1658, 1659, 1660, 1661, 1662, 1663, 1664, 1665, 1666, 1667, 1668 > Used in section 1380.
- < Find needle in *MSortedList* by binary search 402 > Used in section 401.
- < Find needle in *MSortedList* by brute force 403 > Used in section 401.
- < Find the first significant ‘sign’ 795 > Used in section 793.
- < Flush XML output buffer, if full 699 > Used in section 698.
- < Forgetful functor (abstract syntax tree) 938 > Used in section 915.
- < Fraenkel terms (abstract syntax tree) 942, 944 > Used in section 915.
- < Free old arrays, if any 397 > Used in sections 394 and 419.
- < Free the old array, if it isn’t **nil** 494 > Used in section 492.
- < FreePascal declaration of *CtrlSignal* for Windows 165 > Used in section 164.
- < FreePascal implementation of *InitCtrl* for Windows 162 > Used in section 161.
- < GNU License 4 > Used in sections 35, 80, 89, 127, 151, 153, 167, 185, 198, 307, 612, 617, 646, 674, 714, 748, 807, 841, 879, 895, 1030, 1373, 1379, and 1672.
- < Get closed subterm of Fraenkel operator or enumerated set 1702 > Used in section 1695.
- < Get closed subterm of bracketed expression 1700 > Used in section 1695.
- < Get closed subterm of choice operator 1706 > Used in section 1695.
- < Get closed subterm of identifier 1696 > Used in section 1695.
- < Get closed subterm of structure 1698 > Used in section 1695.
- < Get contents of XML start tag 666 > Used in section 665.
- < Get environment variable, Delphi-compatible mode 67 > Used in section 66.
- < Get the identifier number for current word 1381 > Used in section 1380.
- < Get the next digit for dividing arbitrary-precision integers 229 > Used in section 226.
- < Get token kind based off of leading character 659 > Used in section 657.
- < Global variables (**_formats.pas**) 808 > Used in section 807.
- < Global variables declared in **librenv.pas** 618 > Used in section 617.
- < Global variables introduced in **parseraddition.pas** 1382, 1390, 1392, 1407, 1411, 1414, 1420, 1423, 1427, 1436, 1448, 1453, 1467, 1477, 1488, 1496, 1500, 1508, 1516, 1518, 1520, 1526, 1528, 1547, 1550, 1554, 1574 > Used in section 1379.
- < Global variables publicly declared in **wsmarticle.pas** 1187 > Used in section 1030.

- ⟨ Guess the k^{th} functor format 1604 ⟩ Used in section 1598.
- ⟨ Guess *MizFiles* from environment variables or executable path 645 ⟩ Used in section 644.
- ⟨ Halt: invalid article name 76 ⟩ Used in section 75.
- ⟨ Halt: we can't open the file 71 ⟩ Used in section 70.
- ⟨ Handle runtime error cases for *monitor.pas* 156 ⟩ Used in section 155.
- ⟨ Hard delete entry *I* 456 ⟩ Used in section 455.
- ⟨ Has overflow occurred in *NatFunc.Add?* 545 ⟩ Used in section 544.
- ⟨ If cannot open the *FileName*, report an error and halt 136 ⟩ Used in section 135.
- ⟨ If we matched a dictionary entry, then initialize *FoundToken* 780 ⟩ Used in section 779.
- ⟨ Implement *MFormatObj* 838 ⟩ Used in section 810.
- ⟨ Implementation for I/O of XML 676, 679, 681, 685, 689, 694, 700 ⟩ Used in section 674.
- ⟨ Implementation for MScanner 886, 887, 888, 889, 890, 891, 892, 893 ⟩ Used in section 879.
- ⟨ Implementation for *MFormatsList* 826 ⟩ Used in section 810.
- ⟨ Implementation for *_formats.pas* 810 ⟩ Used in section 807.
- ⟨ Implementation for *dicthan.pas* 718, 723, 727, 732, 734, 738, 740, 741 ⟩ Used in section 714.
- ⟨ Implementation for *errhan.pas* 131, 133, 135, 140, 142, 144, 146, 148, 150 ⟩ Used in section 127.
- ⟨ Implementation for *librenv.pas* 620, 623, 628, 630, 632, 634, 638, 639, 643 ⟩ Used in section 617.
- ⟨ Implementation for *mobjects.pas* 308, 309 ⟩ Used in section 307.
- ⟨ Implementation for *monitor.pas* 155, 157 ⟩ Used in section 153.
- ⟨ Implementation for *mstate.pas* 187, 189, 191, 193, 197 ⟩ Used in section 185.
- ⟨ Implementation for *mtime.pas* 168, 171, 173, 175, 177, 178, 180, 184 ⟩ Used in section 167.
- ⟨ Implementation for *pcmizver.pas* 85, 86, 87, 88 ⟩ Used in section 80.
- ⟨ Implementation for *syntax.pas* 843 ⟩ Used in section 841.
- ⟨ Implementation for *wsmarticle.pas* 1034, 1037, 1038, 1041, 1043, 1045, 1049, 1052, 1056, 1058, 1060, 1062, 1065, 1067, 1069, 1071, 1074, 1076, 1078, 1081, 1087, 1090, 1092, 1094, 1097, 1098, 1105, 1107, 1109, 1111, 1114, 1116, 1118, 1120, 1122, 1127, 1129, 1131, 1133, 1135, 1137, 1139, 1141, 1143, 1145, 1147, 1149, 1151, 1153, 1155, 1157, 1159, 1161, 1163, 1165, 1168, 1170, 1172, 1174, 1176, 1178, 1180, 1182, 1184, 1185, 1186, 1188, 1193, 1195, 1196, 1197, 1198, 1199, 1200, 1201, 1202, 1203, 1204, 1205, 1206, 1207, 1222, 1223, 1224, 1225, 1238, 1239, 1240, 1241, 1247, 1248, 1249, 1250, 1251, 1252, 1253, 1254, 1255, 1256, 1257, 1258, 1259, 1260, 1275, 1278, 1279, 1280, 1281, 1282, 1283, 1284, 1285, 1286, 1287, 1288, 1289, 1290, 1291, 1292, 1293, 1294, 1295, 1298, 1299, 1300, 1301, 1302, 1303, 1304, 1305, 1306, 1307, 1308, 1309, 1310, 1311, 1312, 1313, 1314, 1315, 1316, 1317, 1318, 1319, 1320, 1321, 1322, 1323, 1324, 1325, 1326, 1327, 1329, 1330, 1331, 1332, 1333, 1334, 1335, 1336, 1337, 1338, 1339, 1340, 1341, 1342, 1343, 1344, 1345, 1346, 1347, 1348, 1349, 1350, 1351, 1352, 1353, 1354, 1355, 1356, 1357, 1358, 1359, 1360, 1361, 1362, 1363, 1364, 1365, 1366, 1367, 1368, 1369, 1370, 1371, 1372 ⟩ Used in section 1030.
- ⟨ Implementation for *mconsole.pas* 96, 98, 100, 103, 105, 107, 109, 111, 113, 114, 116, 119, 121, 123, 126 ⟩ Used in sections 89 and 117.
- ⟨ Implementation for *scanner.pas* 750, 752, 754, 755, 756, 759, 760, 762, 763, 765, 768, 769, 773, 788, 789, 791, 793, 802, 803, 804, 805, 806 ⟩ Used in section 748.
- ⟨ Implementation of XML Parser 650, 651, 652, 654, 656, 657, 660, 662, 668, 670, 671 ⟩ Used in section 646.
- ⟨ Implementation of abstract syntax 896 ⟩ Used in section 895.
- ⟨ Implementation of parser additions 1380 ⟩ Used in section 1379.
- ⟨ Implementation of *parser.pas* 1673, 1676, 1677, 1679, 1680, 1682, 1683, 1684 ⟩ Used in section 1672.
- ⟨ Implementing formula AST 971, 973, 975, 977, 979, 981, 983, 985, 987, 989, 991, 993, 995, 997, 999, 1001, 1003, 1005, 1007, 1009 ⟩ Used in section 896.
- ⟨ Implementing term AST 917, 919, 921, 923, 925, 927, 929, 931, 933, 935, 937, 939, 941, 943, 945, 947, 949, 951, 953, 955 ⟩ Used in section 896.
- ⟨ Implementing type AST 959, 961, 963, 965, 967 ⟩ Used in section 896.
- ⟨ Import units for *mconsole.pas* 90 ⟩ Used in section 89.
- ⟨ Incorrect term (abstract syntax tree) 954 ⟩ Used in section 915.
- ⟨ Index first character appearances among definitions 758 ⟩ Used in section 756.
- ⟨ Inference kinds (*wsmarticle.pas*) 1054 ⟩ Used in section 1047.
- ⟨ Infix term (abstract syntax tree) 922 ⟩ Used in section 915.

- ⟨ Initialize WS Mizar article 1383 ⟩ Used in section 1380.
- ⟨ Initialize *lKind*, but exit if dictionary line contains invalid symbol 719 ⟩ Used in section 718.
- ⟨ Initialize `errhan.pas` state variables 137 ⟩ Used in sections 135 and 140.
- ⟨ Initialize `main extBlock` instance 1388 ⟩ Used in section 1386.
- ⟨ Initialize “proper text” `extBlock` instance 1391 ⟩ Used in section 1386.
- ⟨ Initialize default values for `extBlock` instance 1387 ⟩ Used in section 1386.
- ⟨ Initialize explicit priority for functor entry in dictionary 726 ⟩ Used in section 724.
- ⟨ Initialize extended item by *ItemKind* 1410, 1413, 1415, 1417, 1419, 1422, 1426 ⟩ Used in sections 1406 and 1424.
- ⟨ Initialize identifier names from `.idx` file 1192 ⟩ Used in section 1188.
- ⟨ Initialize symbol priorities, determine last *ll*, *pl* values 1608 ⟩ Used in section 1607.
- ⟨ Initialize the fields for newly allocated `extItem` object 1409 ⟩ Used in section 1406.
- ⟨ Initialize the *ExitProc* 195 ⟩ Used in section 193.
- ⟨ Initialize *Bl*, **goto** *AfterBalance* if term has at most one argument 1603 ⟩ Used in section 1598.
- ⟨ Initialize *MizFiles* 644 ⟩ Used in section 643.
- ⟨ Initialize *To.Right* and *ArgsLength* arrays 1601, 1602 ⟩ Used in section 1598.
- ⟨ Initialize explicit infinitive for a predicate entry in dictionary 725 ⟩ Used in section 724.
- ⟨ Insert $(X, 1)$ 533 ⟩ Used in section 532.
- ⟨ Insert item to the end of the caller 393 ⟩ Used in section 392.
- ⟨ Int relation implementation 498, 499, 500, 501, 502, 503, 504, 505 ⟩ Used in section 309.
- ⟨ Interface for `errhan.pas` 128, 130, 132, 134, 139, 141, 143, 145, 147, 149 ⟩ Used in section 127.
- ⟨ Interface for `mstate.pas` 186, 188, 192, 196 ⟩ Used in section 185.
- ⟨ Interface for `mtime.pas` 172, 174, 176, 179, 183 ⟩ Used in section 167.
- ⟨ Interface for `syntax.pas` 848 ⟩ Used in section 841.
- ⟨ Interface for abstract syntax 897 ⟩ Used in section 895.
- ⟨ Interface for accommodator command line options 92, 95, 99 ⟩ Used in section 89.
- ⟨ Interface for other command line options 93, 104 ⟩ Used in section 89.
- ⟨ Interface for transfer-specific command line options 106 ⟩ Used in section 89.
- ⟨ Interface for *MakeEnv* command line options 102 ⟩ Used in section 89.
- ⟨ Internal forgetful functors (abstract syntax tree) 940 ⟩ Used in section 915.
- ⟨ Internal selector term (abstract syntax tree) 934 ⟩ Used in section 915.
- ⟨ Item object implementation 864, 865, 868 ⟩ Used in section 843.
- ⟨ ItemKinds (`syntax.pas`) 862 ⟩ Used in section 848.
- ⟨ Keep parsing as long as there is an infix operator to the right 1718 ⟩ Used in section 1716.
- ⟨ Load all tokens from the dictionary 757 ⟩ Used in section 756.
- ⟨ Local constants for `parser.pas` 1674, 1678 ⟩ Used in section 1673.
- ⟨ Local variables for parser additions 1389, 1408, 1412, 1418, 1421, 1424, 1425, 1428, 1432, 1438, 1440, 1442, 1449, 1451, 1454, 1458, 1464, 1472, 1478, 1482, 1489, 1497, 1511, 1562, 1569 ⟩ Used in section 1379.
- ⟨ Long division of *a* by *b* 227 ⟩ Used in section 226.
- ⟨ MScanner object class 792 ⟩ Used in section 749.
- ⟨ MToken object class 761 ⟩ Used in section 749.
- ⟨ MTokeniser class 764 ⟩ Used in section 749.
- ⟨ Main parse method (`parser.pas`) 1921 ⟩ Used in section 1673.
- ⟨ Mark schema proof as “skipped” 1400 ⟩ Used in section 1399.
- ⟨ Method declarations for Item object 867 ⟩ Used in section 863.
- ⟨ Methods implemented by subclasses of *SubexpObj* 876, 1567 ⟩ Used in sections 877 and 1568.
- ⟨ Methods overridden by extended Item class 866, 1404 ⟩ Used in sections 867 and 1405.
- ⟨ Modules used by `mizenv.pas` 37 ⟩ Used in section 35.
- ⟨ Multiply i^{th} digit of *a* by *y* 220 ⟩ Used in section 219.
- ⟨ Multiply i^{th} digit of *b1* to *a1* and add it to *r* 223 ⟩ Used in section 221.
- ⟨ NatSeq implementation 548 ⟩ Used in section 309.
- ⟨ Negated adjective AST constructor 910 ⟩ Used in section 896.
- ⟨ Negated adjective expression (abstract syntax tree) 909 ⟩ Used in section 897.

- ⟨ Non-windows FreePascal implemenation for *InitCtrl* 160 ⟩ Used in section 159.
- ⟨ Numeral term (abstract syntax tree) 920 ⟩ Used in section 915.
- ⟨ One-argument term (abstract syntax tree) 930 ⟩ Used in section 915.
- ⟨ Open `mml.ini` file 640 ⟩ Used in section 639.
- ⟨ Parse XML end tag 667 ⟩ Used in section 665.
- ⟨ Parse XML for formula with binary connective 1296 ⟩ Used in section 1295.
- ⟨ Parse XML for predicate-based formula 1297 ⟩ Used in section 1295.
- ⟨ Parse “equals” definiens 1877 ⟩ Used in section 1872.
- ⟨ Parse “means” definiens 1873 ⟩ Used in section 1872.
- ⟨ Parse “over” and any structure arguments, if any 1861 ⟩ Used in section 1858.
- ⟨ Parse “proof” block 1833 ⟩ Used in section 1832.
- ⟨ Parse “suppose” or “case” block 1827 ⟩ Used in section 1821.
- ⟨ Parse “take” statement for linear reasoning 1818 ⟩ Used in section 1817.
- ⟨ Parse “then” for linear reasoning 1820 ⟩ Used in section 1817.
- ⟨ Parse “thus” and “hence” for linear reasoning 1819 ⟩ Used in section 1817.
- ⟨ Parse “equals” definition-by-cases 1879 ⟩ Used in section 1877.
- ⟨ Parse “means” definition-by-cases 1875 ⟩ Used in section 1873.
- ⟨ Parse a Fraenkel operator 1703 ⟩ Used in section 1702.
- ⟨ Parse a “deffunc” 1807 ⟩ Used in section 1805.
- ⟨ Parse a “defpred” 1809 ⟩ Used in section 1805.
- ⟨ Parse a “reconsider” statement 1813 ⟩ Used in section 1805.
- ⟨ Parse a “set” constant definition 1811 ⟩ Used in section 1805.
- ⟨ Parse an enumerated set 1705 ⟩ Used in section 1702.
- ⟨ Parse ancestors of structure, if there are any 1859 ⟩ Used in section 1858.
- ⟨ Parse arguments for attribute expression 1897 ⟩ Used in section 1895.
- ⟨ Parse arguments to the right 1722 ⟩ Used in section 1720.
- ⟨ Parse bracket functor pattern 1851 ⟩ Used in section 1847.
- ⟨ Parse collective assumption 1780 ⟩ Used in section 1779.
- ⟨ Parse comma-separated variables for quantified variables 1740 ⟩ Used in section 1739.
- ⟨ Parse conditional registration cluster 1902 ⟩ Used in section 1898.
- ⟨ Parse contents of “suppose” block 1828 ⟩ Used in section 1827.
- ⟨ Parse definiens 1872 ⟩ Used in section 1870.
- ⟨ Parse definitions (`parser.pas`) 1868, 1869, 1870, 1880, 1881, 1883, 1885, 1887, 1892, 1895, 1898, 1904, 1906, 1908, 1910, 1911, 1913, 1914 ⟩ Used in section 1673.
- ⟨ Parse equation or (possibly infix) predicate 1756 ⟩ Used in section 1752.
- ⟨ Parse existential registration cluster 1903 ⟩ Used in section 1898.
- ⟨ Parse expressions (`parser.pas`) 1687, 1688, 1689, 1690, 1691, 1695, 1713, 1714, 1716, 1724, 1727, 1735, 1736, 1737, 1738, 1739, 1742, 1744, 1746, 1747, 1751, 1752, 1760, 1766, 1767, 1768, 1769, 1770, 1772 ⟩ Used in section 1673.
- ⟨ Parse field for the structure definition 1866 ⟩ Used in section 1864.
- ⟨ Parse forgetful functor or choice of structure type 1709 ⟩ Used in section 1706.
- ⟨ Parse formula with “does not” or “do not” 1757 ⟩ Used in section 1752.
- ⟨ Parse formula with “is not” or “is not” 1758 ⟩ Used in section 1752.
- ⟨ Parse functor registration cluster 1900 ⟩ Used in section 1898.
- ⟨ Parse infix functor pattern 1849 ⟩ Used in section 1847.
- ⟨ Parse item for notation block 1893 ⟩ Used in section 1892.
- ⟨ Parse item in definition block 1888 ⟩ Used in section 1887.
- ⟨ Parse iterative equations 1834 ⟩ Used in section 1832.
- ⟨ Parse justification for scheme 1920 ⟩ Used in section 1915.
- ⟨ Parse left arguments in a formula 1754 ⟩ Used in section 1752.
- ⟨ Parse library references 1794 ⟩ Used in section 1792.
- ⟨ Parse loci, assumptions, unexpected items in a definition block 1891 ⟩ Used in section 1888.
- ⟨ Parse mode as radix type 1729 ⟩ Used in section 1727.

- ⟨ Parse mode definition 1871 ⟩ Used in section 1870.
- ⟨ Parse multi-predicate with “does” or “do” in copula 1748 ⟩ Used in section 1747.
- ⟨ Parse next block 1923 ⟩ Used in section 1922.
- ⟨ Parse optional left-paren 1733 ⟩ Used in section 1727.
- ⟨ Parse pattern for “set” as a mode 1840 ⟩ Used in section 1838.
- ⟨ Parse pattern for a mode symbols 1842 ⟩ Used in section 1838.
- ⟨ Parse patterns (**parser.pas**) 1835, 1837, 1838, 1843, 1845, 1847, 1853, 1856, 1858 ⟩ Used in section 1673.
- ⟨ Parse post-qualified comma-separated list of variables 1693 ⟩ Used in section 1692.
- ⟨ Parse pragmas and begins 1924 ⟩ Used in section 1923.
- ⟨ Parse predicate pattern 1855 ⟩ Used in section 1853.
- ⟨ Parse private formula 1762 ⟩ Used in section 1760.
- ⟨ Parse proper text 1922 ⟩ Used in section 1921.
- ⟨ Parse reference to scheme from MML 1798 ⟩ Used in section 1796.
- ⟨ Parse scheme block (**parser.pas**) 1915 ⟩ Used in section 1673.
- ⟨ Parse scheme parameters 1917 ⟩ Used in section 1915.
- ⟨ Parse scheme premises 1919 ⟩ Used in section 1915.
- ⟨ Parse segment of fixed variables 1783 ⟩ Used in section 1782.
- ⟨ Parse selector functor 1708 ⟩ Used in section 1706.
- ⟨ Parse semicolon-separated items in a notation block 1894 ⟩ Used in section 1893.
- ⟨ Parse simple Fraenkel expression or “the set” 1711 ⟩ Used in section 1706.
- ⟨ Parse simple justifications (**parser.pas**) 1791, 1796, 1800 ⟩ Used in section 1673.
- ⟨ Parse single reference 1792 ⟩ Used in section 1791.
- ⟨ Parse singule assumption 1781 ⟩ Used in section 1779.
- ⟨ Parse start of XML tag 669 ⟩ Used in section 668.
- ⟨ Parse statement of linear reasoning 1817 ⟩ Used in section 1816.
- ⟨ Parse statements and reasoning (**parser.pas**) 1802, 1803, 1804, 1805, 1815, 1816, 1821, 1830, 1832 ⟩ Used in section 1673.
- ⟨ Parse structure as radix type 1731 ⟩ Used in section 1727.
- ⟨ Parse term subexpressions (**parser.pas**) 1720 ⟩ Used in section 1736.
- ⟨ Parse the command-line arguments for article name and options 194 ⟩ Used in section 193.
- ⟨ Parse the fields of the structure definition 1864 ⟩ Used in section 1858.
- ⟨ Partial Binary integer Functions 580 ⟩ Used in section 309.
- ⟨ Partial integer function implementation 507, 527 ⟩ Used in section 309.
- ⟨ Partial integers to Pair of integers Functions 598 ⟩ Used in section 309.
- ⟨ Pattern objects (**wsmarticle.pas**) 1113, 1115, 1117, 1119, 1121 ⟩ Used in section 1110.
- ⟨ Placeholder term (abstract syntax tree) 918 ⟩ Used in section 915.
- ⟨ Pop **skips** remaining cases 1431 ⟩ Used in section 1430.
- ⟨ Pop a “let” statement 1443 ⟩ Used in section 1430.
- ⟨ Pop a conclusion or regular statement 1441 ⟩ Used in section 1430.
- ⟨ Pop a definition item 1444, 1445, 1446, 1447, 1450 ⟩ Used in section 1430.
- ⟨ Pop a proof step 1434, 1435, 1437, 1439 ⟩ Used in section 1430.
- ⟨ Pop a registration item 1452, 1455 ⟩ Used in section 1430.
- ⟨ Pop a token from the underlying tokens stack 790 ⟩ Used in sections 789 and 789.
- ⟨ Populate global variables with XML entities 1189 ⟩ Used in section 1188.
- ⟨ Populate the current line 796 ⟩ Used in section 795.
- ⟨ Populate *fList* with the command-line arguments 636 ⟩ Used in sections 634 and 638.
- ⟨ Populate *fList* with the contents of *FileName* and exit 635 ⟩ Used in sections 634 and 638.
- ⟨ Predicate declarations for arbitrary-precision arithmetic 278, 280, 282 ⟩ Used in section 198.
- ⟨ Prepare to read in the contents of XML file 655 ⟩ Used in section 654.
- ⟨ Private functor term (abstract syntax tree) 928 ⟩ Used in section 915.
- ⟨ Process “case” (local procedure) 1822 ⟩ Used in section 1821.
- ⟨ Process attributes (**parser.pas**) 1725 ⟩ Used in section 1724.

- ⟨ Process miscellany (**parser.pas**) 1774, 1775, 1776, 1777, 1778, 1779, 1782, 1785, 1787, 1789, 1790 ⟩ Used in section 1673.
- ⟨ Process post-qualified segment 1692 ⟩ Used in section 1691.
- ⟨ Public constants for **dicthan.pas** 715 ⟩ Used in section 714.
- ⟨ Public constants for **syntax.pas** 842 ⟩ Used in section 848.
- ⟨ Public declaration for Stream Object 680 ⟩ Used in section 675.
- ⟨ Public declaration for Text Stream Object 684 ⟩ Used in section 675.
- ⟨ Public declaration for XML Output Stream 693 ⟩ Used in section 675.
- ⟨ Public function declarations for **dicthan.pas** 717 ⟩ Used in section 714.
- ⟨ Public function declarations for **librenv.pas** 627, 629, 631, 633, 637 ⟩ Used in section 617.
- ⟨ Public functions for **pcmizver.pas** 84 ⟩ Used in section 80.
- ⟨ Public interface for MScanner 880, 882, 883 ⟩ Used in section 879.
- ⟨ Public interface for XML Input Stream 688 ⟩ Used in section 675.
- ⟨ Public interface for **mobjects.pas** 310, 311, 312, 317, 321, 322, 349, 370, 387, 409, 423, 428, 437, 441, 449, 451, 452, 485, 486, 497, 506, 528, 547, 552, 568, 579, 597, 611 ⟩ Used in section 307.
- ⟨ Public procedures for **syntax.pas** 849 ⟩ Used in section 848.
- ⟨ Public procedures implementation for **syntax.pas** 844, 845, 846, 847 ⟩ Used in section 843.
- ⟨ Public variables for **syntax.pas** 850 ⟩ Used in section 848.
- ⟨ Publicly declared constants in **wsmarticle.pas** 1035 ⟩ Used in section 1030.
- ⟨ Publicly declared functions in **wsmarticle.pas** 1033 ⟩ Used in section 1030.
- ⟨ Publicly declared types in **wsmarticle.pas** 1032, 1036, 1042, 1044, 1047, 1048, 1050, 1051, 1055, 1057, 1059, 1061, 1064, 1066, 1068, 1070, 1073, 1075, 1077, 1080, 1086, 1089, 1091, 1093, 1095, 1096, 1104, 1106, 1108, 1110, 1126, 1128, 1130, 1132, 1134, 1136, 1138, 1140, 1142, 1144, 1146, 1148, 1150, 1152, 1154, 1156, 1158, 1160, 1162, 1164, 1167, 1169, 1171, 1173, 1175, 1177, 1179, 1181, 1183, 1194, 1277, 1328 ⟩ Used in section 1030.
- ⟨ Qualified segment (abstract syntax tree) 901, 903, 905 ⟩ Used in section 897.
- ⟨ Qualified segment AST constructor 902, 904, 906 ⟩ Used in section 896.
- ⟨ Qualified term (abstract syntax tree) 946 ⟩ Used in section 915.
- ⟨ Raise error over invalid term subexpression 1721 ⟩ Used in section 1720.
- ⟨ Rational arithmetic declarations 258, 260, 262, 264, 266, 268, 270, 272, 274 ⟩ Used in section 198.
- ⟨ Read formats from an XML input stream 837 ⟩ Used in section 810.
- ⟨ Read line into vocabulary from dictionary file 737 ⟩ Used in section 736.
- ⟨ Rebalance the long term tree 1598 ⟩ Used in section 1597.
- ⟨ Replace end of long line with record separator 797 ⟩ Used in section 796.
- ⟨ Replace every invalid character in current line with the unit character 798 ⟩ Used in section 796.
- ⟨ Report hours and minutes 182 ⟩ Used in section 180.
- ⟨ Report results to command line 108, 110, 112, 115, 117, 118, 120, 122, 125 ⟩ Used in section 89.
- ⟨ Reset reserved keywords 1191 ⟩ Used in section 1188.
- ⟨ Return *false* if any item of *Self* is in *fFunc* 526 ⟩ Used in section 524.
- ⟨ Return *false* if any item of *fFunc* is in *Self* 525 ⟩ Used in section 524.
- ⟨ Round to nearest second 181 ⟩ Used in section 180.
- ⟨ Scan for pragmas, and exit if we found one 800 ⟩ Used in section 796.
- ⟨ Selector term (abstract syntax tree) 932 ⟩ Used in section 915.
- ⟨ Set current position to first line, first column 138 ⟩ Used in sections 135, 140, and 187.
- ⟨ Set *lResult* to the index of the newly inserted string 458 ⟩ Used in section 457.
- ⟨ Shift entries of *MCollection* to the left by one 354 ⟩ Used in section 352.
- ⟨ Shift entries to the right by one 358 ⟩ Used in section 356.
- ⟨ Simple term (abstract syntax tree) 916 ⟩ Used in section 915.
- ⟨ Skip all **end** tokens, report errors 1925 ⟩ Used in section 1923.
- ⟨ Skip comments 801 ⟩ Used in section 796.
- ⟨ Skip whitespace for XML parser 658 ⟩ Used in section 657.
- ⟨ Slice pragmas 774 ⟩ Used in section 773.
- ⟨ Spell an error or EOF for the MTokeniser 767 ⟩ Used in section 765.

- ⟨ Spell an identifier for the MTokeniser 766 ⟩ Used in section 765.
- ⟨ Stacked object implementation 450 ⟩ Used in section 309.
- ⟨ Store XML version of vocabulary word 1190 ⟩ Used in section 1189.
- ⟨ String collection implementation 438 ⟩ Used in section 309.
- ⟨ String list implementation 454, 457, 460 ⟩ Used in section 309.
- ⟨ Subexpression constructor 874 ⟩ Used in section 843.
- ⟨ Subexpression destructor 875 ⟩ Used in section 843.
- ⟨ Subexpression object class 873 ⟩ Used in section 848.
- ⟨ Subexpression procedures 878 ⟩ Used in section 843.
- ⟨ Subtract the i^{th} digit of $b1$ from $a1$ 218 ⟩ Used in section 215.
- ⟨ Swap $a1$ and $b1$ if $b1 \leq a1$ 217 ⟩ Used in section 215.
- ⟨ Symbol for vocabulary 722 ⟩ Used in section 716.
- ⟨ Synchronize after missing ‘suppose’ or ‘case’ token 1829 ⟩ Used in section 1827.
- ⟨ Terms with arguments (abstract syntax tree) 924 ⟩ Used in section 915.
- ⟨ Test if one arbitrary-precision number is less than or equal to another 206, 208, 209, 210 ⟩ Used in section 198.
- ⟨ Timing utilities **uses** for Delphi 169 ⟩ Used in section 168.
- ⟨ Timing utilities **uses** for FreePascal 170 ⟩ Used in section 168.
- ⟨ Token kinds for MScanner 884 ⟩ Used in section 880.
- ⟨ Token names for MScanner 885 ⟩ Used in section 882.
- ⟨ Token object class 751 ⟩ Used in section 749.
- ⟨ Token type for MScanner 881 ⟩ Used in section 880.
- ⟨ Tokens collection class 753 ⟩ Used in section 749.
- ⟨ Transform XML entity into character, if encountering an XML entity at i 678 ⟩ Used in section 677.
- ⟨ Trim leading zeros from arbitrary-precision integers 200 ⟩ Used in section 198.
- ⟨ Trim leading zeros from numerator and denominator 203 ⟩ Used in section 201.
- ⟨ Trim whitespace from the right of the current line 799 ⟩ Used in sections 796 and 800.
- ⟨ Try to find a dictionary symbol 779 ⟩ Used in section 773.
- ⟨ Try to read the Mizar version from `mml.ini` 641 ⟩ Used in section 639.
- ⟨ Try to synchronize after failing to find initial ‘case’ or ‘suppose’ 1825 ⟩ Used in section 1821.
- ⟨ Tuples of integers 487, 488, 489, 490, 491, 492, 495, 496 ⟩
- ⟨ Type declarations for XML I/O 675 ⟩ Used in section 674.
- ⟨ Type declarations for `xml.parser.pas` 648 ⟩ Used in section 646.
- ⟨ Type declarations for scanner 749 ⟩ Used in section 748.
- ⟨ Types for arbitrary-precision arithmetic 256, 276 ⟩ Used in section 198.
- ⟨ Types of `xml_dict.pas` 613, 615 ⟩ Used in section 612.
- ⟨ Units used by `monitor.pas` 154 ⟩ Used in section 153.
- ⟨ Update content of $nLastWSItem$ based on type of item popped 1430 ⟩ Used in section 1429.
- ⟨ Update max arguments for structure symbol, if needed 1863 ⟩ Used in section 1858.
- ⟨ Variable (abstract syntax tree) 898 ⟩ Used in section 897.
- ⟨ Variable AST constructor 899 ⟩ Used in section 896.
- ⟨ Variables for finishing a long term in a subexpression 1606 ⟩ Used in section 1597.
- ⟨ Variables for slicing a phrase 772, 775, 778, 781, 783, 785 ⟩ Used in section 773.
- ⟨ Vocabulary object declaration 733 ⟩ Used in section 716.
- ⟨ Weakly strict Item class 1040 ⟩ Used in section 1036.
- ⟨ Whoops! ID turns out to be invalid, insert an error token, then continue 777 ⟩ Used in section 776.
- ⟨ Whoops! Identifier turned out to be a number! 786 ⟩ Used in section 782.
- ⟨ Whoops! We found an unknown token, insert a 203 error token 787 ⟩ Used in section 773.
- ⟨ Windows implemenation for `CtrlSignal` 164 ⟩ Used in section 161.
- ⟨ Windows implemenation for `InitCtrl` 161 ⟩ Used in section 159.
- ⟨ Within expression AST implementation 1011, 1012, 1013, 1014, 1015, 1016, 1017, 1018, 1019, 1020, 1021, 1022, 1023, 1024, 1025, 1026, 1027, 1028, 1029 ⟩ Used in section 896.
- ⟨ Write symbols to vocabulary XML file 747 ⟩ Used in section 745.

1 Mizar environment	35	12
2 PC Mizar Version	80	21
3 Mizar Console	89	24
1. Parsing command-line arguments	92	25
2. Reporting results to the console	108	29
4 Error handling	127	33
5 Info file handling	151	37
6 Monitor	153	39
7 Time utilities	167	43
8 Mizar internal state	185	47
9 Arbitrary precision arithmetic	198	49
1. Arbitrary-precision integers	199	50
1. Arithmetic operations	211	53
2. Arbitrary-precision rational arithmetic	256	63
3. Rational complex numbers	276	66
1. Arithmetic operations	284	67
4. Comparison functions	302	70
10 Mizar Objects and Data Structures	306	71
1. Base object	312	74
2. Mizar String Object	317	76
3. Mizar List	319	77
4. Mizar Collection Class	349	85
5. Simple Stacked (Extendible) Lists	370	90
6. Sorted lists	387	95
7. Sorted extendible lists	409	104
8. Sorted list of strings	423	109
9. Sorted collections	428	110
10. String collection	437	113
11. Int collections	441	114
12. Stacked list of objects	449	116
13. String list	451	117
14. Tuples of integers	485	125
15. Relations of Integers as finite sets	497	128
16. Finite sets of integers	506	131
17. Function of natural numbers	528	136
18. Sequences of natural numbers	547	143
19. Integer sequences	552	144
20. Integer sets	568	148
21. Partial Binary integer Functions	579	151
22. Partial integers to Pair of integers Functions	597	156
11 XML Dictionary	612	160

12	Environment library	617	162
1.	File descriptors	619	163
2.	Collection of file descriptions	622	164
3.	Check compatibility of Mizar with MML	639	168
13	XML Parser	646	170
1.	XML Scanner Object	653	173
2.	XML Parser	661	176
14	I/O with XML	674	181
15	Vocabulary file dictionaries	714	190
16	Scanner	748	199
1.	Collections of tokens	753	201
2.	Mizar token objects	761	204
3.	Tokeniser	764	205
4.	Scanner Object	792	214
17	Format	807	218
1.	List of formats	825	223
18	Syntax	841	228
1.	Block Object	851	231
2.	Item objects	861	233
3.	Expressions	869	245
4.	Subexpressions	873	246
19	MScanner	879	254
20	Abstract Syntax	894	268
1.	Terms (abstract syntax tree)	913	274
2.	Types (abstract syntax tree)	956	285
3.	Formulas (abstract syntax tree)	968	288
4.	Within expressions (deferred)	1010	297
21	Weakly strict Mizar article	1030	303
1.	Weakly strict text proper	1035	305
2.	Schemes	1063	314
3.	Private definitions	1072	317
4.	Changing types	1079	319
5.	Proof steps	1082	321
6.	Structures	1100	325
7.	Patterns	1112	329
8.	Definitions	1123	332
9.	Registrations	1166	345
10.	Helper functions	1185	350
11.	Writing WSM XML files	1194	353
1.	Emitting XML for types	1201	358
2.	Emitting XML for formulas	1207	362
3.	Emitting XML for Terms	1222	368
4.	Emitting XML for text items	1238	375
12.	Reading WSM files (deferred)	1277	399
1.	Parsing types	1287	403
2.	Parsing formulas	1291	404
3.	Parsing terms	1298	408
4.	Parsing text items	1302	410
13.	Prettyprinting WSM files (deferred)	1328	425
22	Detour: Pragmas	1373	448
23	Detour: Parser additions	1379	451
1.	Extended block class	1384	453

2.	Extended item class	1404	458
1.	Constructor	1406	459
2.	Popping	1429	463
3.	Registrations and notations	1457	469
4.	Processing definitions	1466	471
5.	Processing remaining statements	1515	481
3.	Extended subexpression class	1566	494
1.	Parsing Types	1587	499
2.	Parsing operator precedence	1592	501
3.	Processing subexpressions	1609	508
4.	Parsing formulas	1636	514
4.	Extended expression class	1669	523
24	Parser	1672	524
1.	Expressions	1686	528
1.	Terms	1687	528
2.	Types and Attributes	1724	537
3.	Formulas	1739	540
2.	Communication with items	1773	548
3.	Miscellaneous	1774	549
4.	Simple justifications	1791	553
5.	Statements and Reasonings	1802	556
6.	Patterns	1835	564
7.	Definitions	1868	570
8.	Scheme blocks	1915	582
9.	Main parse procedure	1921	584
	Index	1926	586
